These splendid plants should be more widely grown. They want space, for the glossy leaves are 5 ft. to 6 ft. in length. A sloping bank in deep sandy soil they seem thoroughly to enjoy, though in any warm soil they do well on the flat. They are in bloom throughout August and till late in September. No flower is of finer effect for cutting and they last as long in water as on the plant. For arranging them indoors it is worth while growing a patch of one of the Maize-like Sorghums, such as the French Sorgho à bôles; the foliage is not so large as that of Maize and it is also of use in the same way with Dahlias or any of the bolder flowers of late summer.—G. J.

A WONDERFUL BRANCH LOAD OF BULLACES.

AN AMAZING CROP.

I AM now sending you a few particulars of the Bullace tree of which Mr. Peter R. Barr recently sent you a branch. Its height is about 15 ft. to 18 ft.; its age unknown, but thirty years at least. The soil is loamy, with a good deal of gravel, and the tree one of several (mostly Green Gages) all growing one into the other, and much neglected and standing in the middle of my kitchen garden of half an acre at Harston, five miles south-west of Cambridge. What no doubt has assisted in producing this enormous crop (of everything) is the recent boring of an artesian well. I had to have two "blows-out," and consequently the garden was twice flooded. But, of course, we are "smothered" in Plums, Apples and Pears of all sorts. The branch you have was taken at random.—W. FISHER.

"THE LACHENALIA IN NATURE."

I SEE from your issue of August 5 (page 358), which has just reached me, that I must have made a most stupid slip in my letter which you were good enough to publish. The subject of the letter was the *Nerine* and not *Lachenalia*, and I must apologise for the mistake. The account would not have been at all correct as regards *Lachenalia*, the various species of which, as far as I have met them, are confined to low-lying situations.—LIONEL BAKER, *Groot Drakenstein, Cape of Good Hope*.

FORTHCOMING EVENTS.

September 28.—Royal Botanic Society's Meeting. Bristol and District Gardeners' Association's Meeting. Wargrave and District Gardeners' Society's Meeting.

CRINUM POWELLII NINE MONTHS AFTER REPLANTING.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Mushrooms.—To provide an autumn and further successive crops a house or cellar must be made use of, as by the time additional outside beds are made and brought into a bearing state the weather conditions will be too uncertain. The accumulation of sufficient manure to form a bed generally takes some little time, and during such the material should be turned occasionally to sweeten and be brought to a more equable temperature and suitable condition. A depth of 2ft. or less is enough, and the bed should be put together in even layers and made very firm. Insert spawn when heat of bed is inclined to fall a little at a temperature of about 80°, and complete the bed by putting in of fine new soil on the surface, making this also firm.

Cabbages from seed sown as advised some weeks ago have enjoyed the showery growing weather, and are therefore ready for removal to their permanent quarters. It will not be necessary to allow more than about 15ins. for the development of the generally compact growers forming the early batch, but a few additional inches may be given the successive lots.

Parsley.—If not already done and a few frames being available, lift a batch of young, vigorous stuff from the summer sowing and transfer them to the frames, using some good rich soil. At the same time make use of the base of any warm wall or building for more plants should the call for this garnishing herb be constant and heavy all through the winter and early spring.

Beetroot.—The heavy rainfall experienced has tended greatly to the swelling of the mid-season section, and the sooner they are out of the soil the better, for coarseness of growth must inevitably lead to deterioration of flavour. In lifting Beetroot care should always be taken that the main root is not damaged.

The Flower Garden.

Carnations and Pinks layered and inserted as cuttings as advised in an earlier issue will be ready for immediate removal to their flowering quarters. Should autumn planting prove inconvenient, or in the case of Carnations, where heavy loss has been experienced during winter, the layers should be placed in 4in. pots and placed in frames where an abundance of air can be given but dampness warded off. In the case of Pinks which cannot be finally dealt with at present, they may be accommodated in lines in a nursery bed. The present time is suitable also for the lifting, dividing and replanting of old clumps of Pinks should such be necessary.

Cuttings of Violas, Pentstemons and Calceolarias may now be taken, dibbling them all in sandy soil in cold frames a few inches apart.

Lifting.—Bedding plants of Heliotropes, Fuchsias, Pelargoniums, etc., which have been grown as specimen plants (and often this is the work of several years) must soon receive attention, as a few sharp frosts are often experienced by the end of the month. In many cases it may be possible by having protecting material at hand and conveniently arranged to allow such lifting to wait until the latter part of October, but without such it is unwise to risk what it may take years to replace.

Hedges.—It may be necessary to give a final trim up where growth has been somewhat free since the main trimming was carried out owing to climatic conditions being so very favourable for shrub growth. Do not use the shears upon such as Laurel, but rather make knife or scateurs answer the purpose.

Fruits Under Glass.

Late Grapes.—The present season has probably been as unfavourable for these as last year was favourable, and unless a fairly free and judicious use has been made of fire-heat to balance the great scarcity of sunshine, I fear that many growers will have only moderately finished produce, which in its turn will mean only moderate prospects for late keeping. Where the fruit is very backward much may yet be done for several weeks to improve matters by strict attention to the maintenance of an even, buoyant atmosphere brought about by keeping a good warmth in the pipes and a careful use of the ventilators. All unnecessary lateral growths should be rigidly suppressed, thus freeing the plants' energies to ripen fruit and wood.

Melons.—Here again lack of sunshine has told its tale, and growth of the late plants may easily

have been much better. Failing sunshine, plenty of pipe heat must be used to grow Melons satisfactorily, or the results will be poor and the flavour quite second-rate. Where the fruits are approaching the ripening stage maintain a warm moving atmosphere and water only to prevent flagging.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Lifting Onions.—No hard and fast rule obtains as to the date when all the bulbs in a bed may be lifted, as some Onions mature much earlier than others. But in cases where the foliage has died down there is nothing to be gained by keeping them in the ground any longer. In ripening the bulbs a convenient method is to tie in bunches of six and hang over a wire so that they may get full advantage of sun and air to further the drying process. Lay aside bulbs that may have sustained slight damage for immediate use, and in due course store the crop in an airy, frost-proof shed.

Globe Artichokes.—Cut the spent flowers from the plants and assist with a generous watering of liquid manure.

Spring Cabbage.—Complete the planting of Spring Cabbage at the earliest possible moment so that the plants may get established before severe weather sets in.

French Beans.—Where these are growing in pits or frames, attention must be accorded them if the best results are to be obtained. Ventilate freely during the forenoons when the weather is favourable, but when syringing is resorted to the ventilators should be closed early in the afternoon. Where the young plants are inclined to be leggy they should be supported by small, twiggy growths of birch.

Winter Lettuce.—Plants raised from seed sown a few weeks ago are now ready for transferring to frames, and should be encouraged so that all the growth possible may be made before wintry conditions prevail.

Mustard and Cress.—Sowings should now be made in frames so that nice, juicy and tender growths may be had for salading during the autumn.

Parsley in Frames for winter use should be kept clear of weeds and stimulated by occasional waterings with soot water.

The Hardy Fruit Garden.

Root Pruning.—Although somewhat early for this work, a note should be taken of the various trees in need of this treatment, and the work can then be carried through before the end of the month. If the work is done while the trees are in full leaf they quickly recover, new roots being emitted soon after the pruning has been carried through. Where the soil is poor a quantity of good loam should be added. Also add a quantity of old lime rubble as this proves of much assistance to all kinds of stone fruits.

The Pleasure Grounds.

General Work.—Much attention is now necessary in this department if tidiness is to be maintained, owing to falling leaves and the effect of the autumn gales. All rough grass should be scythed wherever possible, as the work of raking leaves later on is thereby considerably reduced. Where lawns have received their final cut for the season they should be well swept and thoroughly rolled.

The Flower Garden.

Mixed Borders.—Annuals which have passed out of flower should be cleared away and the vacant places prepared in readiness for the reception of Wallflowers, Giant Pansies, Myosotis, Canterbury Bells and Sweet Williams.

Violets.—Where these are grown for winter flowering in frames, they should now be lifted with good balls of soil attached and placed in frames occupying a sunny position. Plant about 1ft. apart each way, keeping the foliage as near to the glass as possible. Violets enjoy a generous mixture of soil, that from an old Melon or Cucurbit bed suiting admirably. A sprinkling of old lime rubble may also be added. During the winter ventilate carefully, as damping often causes the loss of many blossoms. Keep red spider in check by syringing the plants frequently with Abol Insecticide or other reliable wash.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

THE GREENHOUSE.

Osmanthus Delavayi.—This plant, although hardy on walls, and even in the open in the south and west, is well worth growing in pots for the unheated greenhouse. In pots it makes neat specimens with small dark evergreen foliage and produces its fragrant white flower in wonderful profusion. The flowers are much larger than any other species of *Osmanthus*. It is easily propagated by means of cuttings at this time, or again during spring; they root readily in sandy soil, standing the pots under a bell glass in a cool house or in a cold frame.

Swainsonia galegifolia and var. *alba* are old greenhouse favourites, but seldom seen in general cultivation at the present day. They are long slender-growing plants and are possibly seen at their best when planted out in the conservatory and trained up pillars. They also make good specimens in large pots if the long growths are kept tied round the supporting stakes. They are easily propagated by means of cuttings which, if rooted at this time will make good plants for next year. The young plants should be pinched several times to induce them to make a number of shoots.

Abutilon insigne.—This is splendid for planting out in the cool conservatory, being ideal for training on overhead rafters. The long slender, flowering shoots hang down in a very graceful manner, while the large dark green rugose leaves are very handsome. Even though it never flowered, the plant is worth growing for its foliage. It is easily propagated at this or any other time by means of twiggy side shoots. The cutting pots should be placed in a close case, with slight bottom heat.

Abutilon vexillarum and its variegated variety are elegant, slender-growing plants, well suited for training on rafters in the conservatory or cool greenhouse. Their slender habit is a great advantage as they do not shade the plants beneath over much. Plants propagated at this time will be ready for planting out next spring. There are many beautiful garden varieties of *Abutilon*, with flowers of varying shades of scarlet, crimson, rose, yellow and white, but they are seldom seen in gardens at the present day. They are rather strong growing for training under the roof, for unless kept well thinned out they cast too much shade on the plants beneath. They are, however, excellent for covering back walls. In such positions they flower more or less all the year round. They can also be grown in pots for the stages. Cuttings rooted at this time make good plants for next year and, if stopped several times, make bushy plants in 6-in. or 7-in. pots.

Climbers on the roof of the conservatory or greenhouse that have finished flowering, should now be partially thinned out, this to allow all the light possible to reach the plants beneath, as it is very essential that all plants should now be freely exposed to light to harden their tissues for the winter. Thus, all shading material should be washed off, and where blinds are in use, they should be dispensed with as soon as possible. They should be carefully dried before being stored away for the winter.

Hippeastrums.—As they complete their growth, bulbs that have attained flowering size should be removed from the plunge bed and be stood out in cold frames, where they should be dried out, keeping the frame lights on, otherwise they should be fully exposed to the sun. They must be stored dry all winter. I find they winter quite well in frames, where the temperature can be kept about 40° to 45° Fah. Young *Hippeastrums* raised from seed this season should now be potted off into sixty sized pots. They should be grown steadily on without drying off until they reach flowering size.

Roses in pots should now be overhauled. Some of the top soil should be removed and the plants top-dressed with good rich soil, to which some fine bone meal has been added. The drainage should be examined and, if necessary, corrected, while any that are in bad condition at the roots should be repotted, using for this purpose good sound loam, with sufficient coarse, clean sand to ensure free drainage. Instead of leaf soil, some old Mushroom bed manure should be added to the compost; failing this, dried cow manure should be used and a 6-in. potful of fine bone meal should be added to every bushful of soil. The dwarf *Polyantha* Roses are excellent for growing in pots. They are all easily raised from cuttings, which may be put in a west border any time next month. They should make fine plants for lifting and potting up next autumn.

J. COURTS.

Royal Botanic Gardens, Kew.

A Shade-loving Alpine.—There are few alpine plants of which the enthusiast is more enamoured than Haberlea rhodopensis, which, upon its introduction, appeared to give huge delight to those who saw it and which has since that time claimed an honoured place among the choicer flowers of the rock garden. It is no bar to its popularity, but rather an incentive to its cultivation that it is a shade-lover and delights most in the cool, sunless parts of the garden, where it will thrive happily, whereas in the open, sunlit areas it suffers from the scorching sunshine and shrivels up unless most carefully tended and shaded from the heat of the day and well supplied with water. In the shade, on the contrary, it makes large, healthy charming foliage and produces plenty of its pretty flowers, which are not inaptly likened to those of the Gloxinia or the Streptocarpus. The deep green, toothed, hairy, thick, felt-like leaves well repay examination in themselves and their rosettes alone are no mean ornament to the rock garden, but the consummation of the plant's beauty lies in the grace and colouring of the lavender or lilac flowers with the spotting of gold which lightens up the colour of the throat and adds an additional charm to these blooms. Then there is a scarce and charming white variety, *H. rhodopensis alba*, although I must confess to preferring the coloured one; while there is also a fine species (variety according to some), which passes under the name of *H. Ferdinandi-Coburgii*, which is specially beautiful. It is not difficult to cultivate in a compost of loam, sand and peat, and is quite at home in a crevice of the rock-work or even between stones on the level. One of the finest plants we have seen was on the north side of a rock garden between stones and shielded from the sun by a shrubby *Spiraea* and partly overhung by the shrub. Here the Haberlea was a picture, with many rosettes of its distinct leaves and numerous lilac flowers. Propagation is effected by careful division of established plants or by seeds, but the seeds and seedlings require most careful treatment.

Trial of Raspberries and other Rubi.—We are informed that the Royal Horticultural Society desires to make a test of (1) Raspberries (both summer and autumn fruiting) and (2) other kinds of Rubi. Five plants of the former and three of the latter of each variety to be tried should be sent to reach The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (Horsley Station, L. and S.W. Railway) by November 30th, 1922. The Director would be obliged if those desiring to send varieties for these trials would let him know the names of the varieties to be sent on the entry forms (which may be obtained from him) by the end of October.

ANSWERS TO CORRESPONDENTS

QUESTIONS AND ANSWERS.—All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant.

FLOWER GARDEN.

TULIPS FOR THE ROCKERY (J. G.).—Write to Messrs. R. Wallace and Co., Limited, The Old Gardens, Tunbridge Wells; Messrs. Barr and Sons, 12, King Street, Covent Garden, W.C.2; and Messrs. John Waterer, Sons and Crisp, Limited, Twyford, Berks, for particulars of copies of their bulb catalogues.

HERBACEOUS PLANTS FOR LONDON GARDEN (N. G., Kenington).—The best of all herbaceous plants for London seems to be the German Iris, for one sees it thriving under many apparently adverse conditions. Besides this, however, a fair number of the harder border plants will do quite well in the district named. A short selection would include *Anemone japonica*, *Aquilegia*, various

Asters (*Michaelmas Daisies*), *Campanula glomerata*, *Centranthus ruber*, the Day Lily (*Hemerocallis flava*), *Echinops Ritro*, the perennial Sunflowers and *Heleniums*, *Lythrum roseum superbum*, *Oenothera eximia*, *speciosa* and *taraxacifolia* (Evening Primroses), the *Megasea Saxifragas* (*S. cordifolia* and *S. crassifolia*), *Geum coccineum* Mrs. Bradshaw and *Rudbeckia Newmanii*.

WATER LILIES ATTACKED (G. J. R., Surrey).—The Water Lilies are attacked by a green fly (a species of aphid), and the best thing to do to get rid of them would be to spray the plants with a nicotine wash or Katakilla, but if the water contains fish these sprays would be fatal to the fish. In that case probably the safest thing to use would be quassa and soft soap.

EDGING FOR FLOWER-BED (B. C. F., Dorset).—*Saxifragas* generally would scarcely be in harmony with the bold habited plants in the bed, though the *Megasea* section would be a suitable exception. For the shaded portion the *St. John's Wort* (*Hypericum calycinum*) would be very suitable and successful. As an alternative or addition to the *Megaseses*, *Alyssum saxatile* and *A. s. citrinum* are to be recommended.

VIOLETS ATTACKED (B. T. T., Staffs.).—The Violets are attacked by the Violet leaf-spot, *Phyllisticta viola*. They should be sprayed with potassium sulphide (diver of sulphur) 1oz. to 4 gallons of water at weekly intervals after removing all the diseased foliage.

TREES AND SHRUBS.

PRUNING LAUREL HEDGE ("Enquirer," Sussex).—If the proposed pruning is not intended to be very severe, it may well be done now; but if it is intended to cut back into the hard wood, this should be delayed until the early spring just before growth recommences, as if done now there is a great danger of the branches bursting into fresh young growth, which would be killed by the winter frosts.

ROSE GARDEN.

ROSES DISEASED (A. G. L., Bournemouth).—The Rose leaves are attacked by the black-spot disease of Roses, due to the fungus *Actinomyces rose*. This is one of the most persistent of Rose diseases, and calls for unremitting attention if it is to be overcome. The best treatment for it is the destruction of all diseased leaves and the spraying of the plants (as a protective measure) with Bordeaux mixture every fortnight or so from May onwards. Some Roses are much more seriously affected by the trouble than others.

THE GREENHOUSE.

CHRYSANTHEMUMS ATTACKED (B. T. T., Staffs.).—The best spray to use for the aphid on the *Chrysanthemums* is nicotine soft soap, made by dissolving 3ozs. of nicotine and 4lb. of soft soap in water and making up to 40 gallons.

GRAPES UNSATISFACTORY (Torquay).—The Vines would receive a serious check when the leaves were scorched by the fumes from the sulphur just at the time when the buds in which the embryo bunches were forming, should receive all the nourishment possible. Prune back the side shoots when the wood is ripe late in December, surface dress the border with lumpy loam and manure mixed after thoroughly clearing away all rubbish, and apply clear water freely. Do not overcrop next year. Several pieces of flannel soaked in petrol and suspended from the wires 2ft. below the Vine foliage will cause wasps to leave the house. Soak the flannel twice weekly.

PEACHES IN POTS (T. F. D.).—Yes, Peaches can be grown successfully in large pots. They require more attention, of course, than trees that are planted out. Large pots are better than tubs, because the soil in them retains moisture better than it does in tubs, and the roots of these fruit trees should never be quite dry. If the trees are to be permanent in the house, brick pits about 2ft. long, 18ins. wide and 2ft. deep would serve better than pots. The latter should be quite 16ins. across. Duchess of Cornwall, Duke of York, Magdala, Dymond, Royal George and Alexandra Noblesse are fine reliable varieties. If it is decided to grow the trees in pots, specimens in pots should be procured and reported if necessary in November. Care should be taken not to subject the trees to great heat, especially early in spring.

PEACH TREE UNSATISFACTORY ("Shirley").—The variety (Late Devonian) is the result of a cross between Belle de Vitry and Late Admirable. The first named is not grown generally and the latter not as much as it used to be, as there are better varieties. Late Devonian is a good variety for September ripening, being large, deep fleshed and juicy when well finished. The great heat last year killed many old trees and crippled others under glass. Our correspondent appears to have done everything necessary to ensure success. Sometimes fruits fail owing to faulty connexion between Peach and stock, the free flow of sap being impeded. We advise our correspondent to give the tree another trial, autumn and winter watering being important as well as summer. Surface mulch next spring with lumpy loam and mix 2 pecks of chalk or 1 peck of lime with the loam, which should be put on 2ins. thick in January at the latest. If the tree disappoints next year, replace it with Peregrine or Grosse Mignonne.

FRUIT GARDEN.

LLOYD GEORGE RASPBERRY (Stoke Prior).—It would be well not to cut off the tops of the canes, even though they are just coming into flower, but rather allow them to remain untouched for the present and shorten them later on. As soon as the fruit had been gathered the old canes should have been removed.

MISCELLANEOUS.

FUMIGANT FOR GREENHOUSE PLANTS (Z. Y. X., Bristol).—If our correspondent insists on his condition as to a preparation absolutely destitute of poisonous

property to human beings or animals, we can only suggest that he sprays the affected plants with quassa and soft soap. There is, however, no difficulty or danger attached to the proper use of a nicotine fumigant, and we should ourselves fumigate with Darlington's Auto-sprays, which are effective, clean to handle and readily used. There is a certainty about nicotine not found in other fumigating preparations, excepting, of course, the deadly hydrocyanic acid gas.

HOW TO DESTROY WASPS ("Mauve Poppy").—In glass structures, or where the fumes of petrol are not objected to, wasps will soon leave such places if several pieces of flannel soaked in petrol are suspended from the roof several feet below. The fumes will not be harmful to fruit, flowers or plants as long as the house is ventilated. To destroy the nests, watch wasps as they leave the garden, following them as far as they can be seen, then stand at that point and watch and follow on again till they are traced to their nests. Mark the latter with pieces of white paper tied to sticks. All wasps are in their nests by 9 o'clock (summer time). Roll up pieces of rags to the size of a finger, one for each nest, soak the rolls in pure turpentine carried in a can. Insert a roll in the hole to each nest as far in as possible. Then immediately cover entrance with a spadeful of soil and make it firm by treading. All wasps will be destroyed in the nests if soil at entrance is not removed. The nests are generally found near water.

TRANSPLANTING IVY (Beginner, Berks.).—The Ivy could well be transplanted from the present time onwards until growth recommences in the spring. The shoots which are clinging to the wall are scarcely likely to attach themselves to the new wall. It would be a good plan to select the best shoots, fasten them to the wall fairly thinly so as to furnish it, and cut the remainder away close to the ground. The selected shoots would break out a considerable way down, and these new growths attach themselves to the wall, while from below new shoots would soon climb up between the older ones and the wall thus become quickly furnished. It is important to be sure that the roots are moist before the moving is commenced, and a good watering should be given as soon as the transplanting is finished. If the weather is very bright, it would be well to shade the Ivy with canvas or sacking during the middle of the day, and it should be syringed morning and evening for a time.

WORMS IN FLOWER-POTS (A. G. H., Broughton-in-Furness).—Prevention is always better than cure, so to ensure that there are no worms in pot plants the soil should be searched for them before it is used for potting. In most greenhouses the pot plants are grown on wooden staging so there is no likelihood of the worms entering the pots while the plants are in the glass houses. All pot plants that are placed in frames or out of doors for the summer should be stood on cinders in order to ensure perfect drainage and also because worms rarely travel through them. To get rid of the worms already in the pots the plants may be watered with lime water, when the worms will soon appear on the surface and may be collected. Another method is to turn the plant out of the pot, when the worms may often be seen. If they are in the middle of the ball of soil they will commence to emerge if the ball is gently smacked a few times or if a stick is thrust into it. The end of the worm should be held firmly for a few moments, when it will be found that the pest relaxes and may be easily withdrawn. No attempt should be made forcibly to extract the worm, as in such case it would break. Heaths and other lime-hating plants must not, of course, be watered with lime-water.

PLANTS FOR EXHIBITION (A. W. E., Cardiff).—A Phlox that should be at its best in our correspondent's district about the third week in July is Princess Alice, a variety bearing huge trusses and large cerise-coloured tips with an almost white centre. This is about the earliest of the *Decussata* section. Of course any of the *Suffruticosa* section would be early enough, but they are not so bold either in size or colour. In regard to Delphiniums, it is more a matter of age of plants and situation than of variety that governs the date at which they are in their prime. Young plants of Millicent Blackmore, The Alake, Bella Donna semi plena, or Smoke of War planted in a position where not more than half a summer's day's sunshine reaches the plants should provide spikes of useful quality at the time required, but it is prudent to grow more than one variety, as seasons and situations are variable. *Spiraea Aruncus* and *Astilbe Ceres* are both herbaceous perennials, and may be shewn as such. The question of eligibility of Sweet Peas in a class for annuals in variety when there are separate classes for Peas rests entirely with the wording of the schedule. The usual intention is to cater for annuals other than Sweet Peas in one class and to confine Sweet Peas to their own class, but unless it is explicitly stated that Sweet Peas are excluded, an exhibitor is perfectly justified in shewing them in the class for eight weeks of annuals in variety.

NAMES OF PLANTS.—X. Y.—Rose Irish Fireflame.
NAMES OF FRUIT.—Stoke Prior.—Plum the Zar probably, but partially rotten on receipt. Pears too immature to name. Send again when mature.—C. H. C., Dorking.—1, White Magnum Bonum; 2, Coe's Golden Drop; 3, Belgian Purple; 4, cannot name from specimen; 5, McLaughlin's Gage; 6, Transparent Gage.—R. A. B., Corle Castle.—Plum Angliana Burdett Gage; Apple, probably Prince Edward, not matured or coloured yet.

BARR'S Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, which are produced in umbels of 6 to 24 blooms, are borne on stout stems varying in height from 1 to 2 feet. In colour they range from *dark red*, *vivid crimson*, *cerise* and *scarlet* to *salmon*, *coral-rose*, *pink*, *blush* and *white*, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

12 in 12 beautiful named varieties .. 42/-, 50/-, 63/- and 84/-
6 in 6 " " " .. 18/-, 24/-, 30/- and 42/-

Street, W.C.2; price 9d. net; by post, 11d.

WOODLAND PLANTING ON LIMY SOIL

WHERE soil is reasonably lime-free, the Rhododendron and its allies form the mainstay of the woodland garden. They go far to provide its floral beauty and at the same time furnish an admirable setting for Lilies and other desirable woodland plants. There is in this country, however, a great extent of woodland or copse of which the soil consists, under a thin stratum of humus-containing loam, of limestone or more frequently chalky marl. Unless planted to timber of comparatively recent years, there is little woodland on the chalk proper. In many cases houses have been built on the confines of such woodland and the owners would naturally wish to incorporate these shady reaches in their garden scheme. The necessity of substantial planting is the more evident when it is pointed out that bulbous plants generally dislike lime. Even the Bluebell of our own woodlands fights shy of noticeably limy soil.

Of furnishing evergreens for undergrowth in such woodland the common Laurels take high place. Colchic or Causasican succeed equally well and their large glossy deep green foliage shews to great advantage in such situations. Common Holly, too, will flourish. The large-leaved forms, such as *Hodginsii* and *Shepherdii* are not so suitable as the common form for undergrowth. The latter, of course, grows laxer and looser in shade than in the open and the leaves come larger, flatter and more attractive in colouring. Neither Holly nor Laurel fruits to any extent in woodland and their flowers, even if produced, are scarcely showy; their value, therefore, rests upon their foliage alone. In a different

category come those evergreen Barberries, *Berberis Darwinii* and *B. stenophylla*, which are admirable for an undergrowth, though they, too, flower less freely than in the open. The Mahonia, too, *Berberis Aquifolium*, is invaluable and the Japanese species, *B. japonica*, which in some forms flowers all winter through.

For the more open places the Escallonias are excellent, especially *E. macrantha* and its nearer relatives. The almost indestructible Rose of Sharon, *Hypericum calycinum*, is an invaluable carpeter and its large golden many-stamened blossoms shew to advantage in the semi-shade. For places where sunshine penetrates—and on limy soils the shade should not anywhere be too dense—the single "Corkrose," *Kerria japonica simplex* is excellent. Its bright green stems make it most effective in winter when destitute of leaf, while in early summer, when the slender arching

canes are thickly spangled with golden blossoms, it is one of the most beautiful of flowering shrubs. It is astonishing how many gardens harbour the bloated double form, which are destitute of this elegant plant.

The Bladder Senna, *Colutea arborescens*, is another plant admirably suited to the wild garden and quite at home upon limy soil. It likes semi-shade, but should not be immured in woodland recesses. Especially if it can get its "feet" to water, the Guelder Rose, *Viburnum Opulus* will flourish and, given a certain amount of sunlight, produce its elegant corymbs of flower and its brilliant red fruits in abundance. The true Brooms—*Cytisus scoparius*, *C. albus* and relatives—are essentially plants for sandy and gravelly soils, but the Spanish Broom, *Spartium junceum*, flourishes even on the chalk. In many parts of England it is not too hardy and the fringe of woodland looking south or west forms a suitable place for it. It should, of course, be planted to receive an abundance of sunlight.

The Privets (*Ligustrum*), object neither to lime nor shade and the oval-leaved Privet is satisfactory as undergrowth, particularly as its berries are quite handsome when freely produced, though they could hardly be classed as showy. The larger-leaved Eastern forms, *L. lucidum* and *japonicum* are also suitable and offer more beauty of flower.

Those best of shrubby Spiraeas, *S. Lindleyana* and *arborescens*, have no objection to lime and are, of course, grateful for a certain amount of shade, while the whole of the *Brunaldia* clan, from the crimson Anthony Waterer to the whitish *callosa alba*, will provide flower for a considerable period.

A NEW CHINESE FLOWERING APPLE, *PYRUS MALUS TRANSITORIA*.

THE EARLY FLOWERING BERBERIS JAPONICA.

FINEST OF SHRUBBY SPIRÆAS, S. LINDLEYANA.

THE CHALK LIKING VIBURNUM TOMENTOSUM MARIESII.

The Cornelian Cherry (*Cornus mascula*) and the Dogwoods (*C. sanguinea* and varieties), all succeed and are admirably suited for woodland planting. Probably all members of this family would succeed.

Groups of that quaint shrub, *Lycostera formosa*, might well be introduced. If planted in neighbouring garden, this invariably turns up in the woodland, doubtless from seeds dropped by birds. Neither flowers, fruits nor bracts are exactly showy, but the green arching canes introduce a pleasing diversity of vegetation without giving an exotic appearance. That so-called *Aralia*, *Fatsia japonica*, does well in woodland. It is less tender than most people believe, but needs a cool exposure, even the shade of trees, whereas, with the idea of sheltering it from cold winds it is often planted in full sunlight. It is quite handsome in flower and fruit, but should be kept for the more sophisticated part of the woodland, because of its distinctly exotic appearance. Where a sufficient opening in the tree canopy exists to admit the requisite sunshine, all the Thorns will flourish. Only single flowered varieties, however, seem to the writer desirable in such a place, though some planters would doubtless have other views. Suitable kinds include *Crataegus Crus-galli* and *C. Douglasii*, *macrantha* and *coccinea*, with the single scarlet form of the common Hawthorn, *C. Oxyacantha* var. *coccinea* of nurseries. Under similar conditions the Judas Tree, *Cercis Siliquastrum* will succeed. The reddish-purple flowers produced before the leaves in spring are not specially beautiful, but the twisted growth of trunk and branches, somewhat similar to that of an old apple tree, but characteristic of the tree in question, make it, when properly employed, a picturesque and valuable feature.

Almost all *Pyruses* enjoy a calcareous soil and, as they often unite beauty of flower with handsome fruits, are worthy of notice where free from drip and not shaded to any extent. The new *P. Malus transitoria* will be found described under New and Rare Plants in this issue.

The Oriental Guelder Rose, *Viburnum tomentosum*, is best represented by the fine variety *Mariesii*, but the totally sterile form, *V. t. plicatum*, which bears the same relation to the typical plant as does the "Whitsun Boss," *V. Opulus* sterile, to the typical Guelder Rose, also succeeds on limy soils.

In late summer a great deal of colour may be afforded by the judicious planting of Clematises. The Clematis likes a sweet soil and a considerable amount of shade, especially to the roots. For this woodland planting *Clematis Jackmani* and the varieties classed with it are most suitable. The typical plant—if we may be forgiven for speaking of a garden variety in such a way—looks beautiful when flinging its shoots aloft in association with that strong-growing *Wichuraiana* Rose *Dorothy Perkins*, and the Rose herself, despite her double flowers, looks happy enough when climbing in the topmost branches of a Silver Birch. This tree, it may be well to point out, may be established even on the chalk. It does not, however, "ped" so well on heavy marly soils as on lighter sandy ones. It has so many beauties, however, that if not already existing, it should certainly be introduced into woodland planting. To return to our Clematises, however! *Jackmani*, *Snow White Jackman* and perhaps *Comtesse de Bouchaud* would be our selection from this class for the purpose in this connexion. Beyond these in not too shady a spot *C. montana* and the flesh pink variety *C. montana rubens* might be tried. The latter has very admirable reddish foliage and young wood. *C. Armandi* would no doubt often survive our winters in woodland where (except against a wall) it perishes in the open garden.

Those two fine early-flowering Heaths *Ericas carnea* and *darleyensis* have no objection to lime in the soil, and the tall *E. mediterranea* has the same happy indifference, while the less showy *E. cinerea* will grow in the humus containing vegetation immediately overlying limestone rock.

A TRIAL OF NEW ROSES

British Introductions of 1920

ALTHOUGH 1920 could well be described as a prolific year as regards the number of new Roses placed on the market, the quality seems to have suffered for the quantity, and very few striking novelties or really first-class Roses were produced. The total number tested here (Oxted, Surrey) was sixty-nine, of which thirty-eight were British and thirty-one foreign.

Although, patriotically, one likes always to give preference to the home-produced article, it behoves us at the same time to watch what the trade growers across the Channel are producing, for, in the interest of the industry, with all new Roses the good must be acclaimed and the bad condemned and discarded for ever.

Would we had a judicial bench, to sit in judgment on all new Roses, entering the good on the roll of accepted and recommended varieties, sentencing the bad to deportation or the fiery furnace and, above all, to keep a full record of what is produced and what becomes of it.

Names should only be allowed which have not been used before, and the too-much-alike varieties would be consigned to the scrap-heap, as well as the undesirables—a simple matter for the powers that be to put into execution, and how amateurs who buy new Roses from the high falutin descriptions in the catalogues would bless them for saving them from buying trash, and helping them to spend their money on new varieties that are really novelties and good ones at that!

The seven points on which new Roses are judged here are: Novelty, growth, form, colour, flowering, foliage and fragrance. The latter essential qualification is, unfortunately, so often lacking that mention is only made of it when it exists. Taking the British Roses first in alphabetical order:

Archie Gray (H.T., Hugh Dickson).—Unfortunately the plant sent us was a poor one and the growth was weak, but it was shewn well at some of the exhibitions. A large, deep crimson bloom, of good shape, and large enough for an exhibition box. Hardly a free bloomer, and the foliage inclined to mildew a little.

Bronze Bedder (H.T., William Paul and Son).—A free-flowering single Rose of bronze colour—quite a novelty. The buds, which are long, pointed and crimson coloured, are exceedingly pretty. Growth is good and foliage clean. Sweet

scented. A good single Rose to mass for a bold effect.

Callisto (Hybrid Musk, J. H. Pemberton).—A strong grower, with branching habit. Small clusters of pale yellow blooms of rosette shape. Summer flowering only. Should be grown as a bush Rose, and is hardly suitable as a bedding variety.

Charm (H.T., William Paul and Son).—Rather a thin, sparse grower. The buds are pretty—reddish orange opening out to pale coppery yellow, semi-single blooms in good trusses. Sweet scented.

Clare d'Escotet (H.T., W. Easlea).—Growth

ORANGE AND APRICOT SHADES, ROSE INDEPENDENCE DAY.

not strong. Blooms are flesh white, rather flat, and inclined to lose their colour. Hardly any call for this as a new variety.

Climbing Chateau de Clos Vougeot (H.T., H. Morse).—Not a strong grower, and at present little sign of climbing at all. The usual horizontal growth of its namesake, but possibly it may start off next season, as some of these climbing Hybrid Teas have a habit of doing.

Climbing Ophelia (H.T., Alex. Dickson and Sons).—An excellent climbing variety of this splendid and popular Rose. Blooms are good and as true as the dwarf variety. The plant started off as if it had made up its mind to climb, unlike some of the so-called climbing Hybrid Teas, of which 50 per cent. never intend to climb at all. It should prove an excellent novelty.

Constance Casson (Perpetua, B. R. Cant and Sons).—A very strong grower, with large, globular blooms of bronze flushed yellow colour. The foliage is very fine, particularly the new growths. The blooms may be strong enough for exhibition, but their shape is inclined to be flat. It should make a splendid bedding Rose, and the colour is decidedly novel.

Dinah (H.T., William Paul and Son).—Our plant of this was a weak one, but in any event it seems to be a small and thin grower. The blooms are deep crimson, but they are inclined to discolour upon maturity. Foliage is clean and good.

Eleanor Henning (H.T., W. Easlea).—Semi-single, salmon pink blooms, with large petals. Medium grower, with good dark foliage. Not a very profuse bloomer, but very sweetly scented.

Esme (H.T., B. R. Cant and Sons).—A good strong grower, with heavy blooms of cream colour, flushed pink on edges of petals reminding one of Mrs. Foley Hobbs. It should make an exhibition Rose, but as a garden Rose a mass of it would be very attractive. Faintly scented.

Florinda Norman Thompson (H.T., Alex. Dickson and Sons).—Excellent growths and a profuse bloomer. Large trusses of lemon yellow flowers flushed rose and globular in shape. Thick, leathery foliage. A fine free bedding Rose.

Havering Rambler (Multiflora, J. H. Pemberton).—Summer flowering only. Very vigorous growth, with heavy trusses of pink and white blooms with bright yellow stamens, but unfortunately the blooms seem to lose colour quickly.

Hawmark Crimson (H.T., Alex. Dickson and Sons).—One of the best of the year's production. A darker coloured Red Letter Day of the same semi-single type, but a stronger grower, with upright stems. Fine long-pointed buds. Well worth growing as a bedding Rose, and a mass of them should be a sight for the gods.

Independence Day (H.T., Bees, Limited).—There seems a little doubt as to whether this is a 1919 or 1920 variety. Origin Mme. E. Herriot - Souvenir de Gustave Prat, but the blooms are held more erect than the former parent. Reddish orange buds, opening out to deep yellow blooms, with bright red stamens. Not a strong grower, but sweet scented.

Jersey Queen (H.T., Jersey Nurseries, Limited).—Strong growth, but apt to be lopsided after the style of Mme. Abel Chatenay—throwing one heavy shoot only. Big trusses of yellowish pink blooms. Sweetly scented.

Lady Anderson (H.T., Alex. Dickson and Sons).—Fair growth. Large coral pink blooms, strong enough for exhibition. Slightly scented.

Lady Maureen Stewart (H.T., Alex. Dickson and Son).—A strong grower, with good trusses of brilliant velvety scarlet blooms, the shape of which reminds one of our old friend A. K. Williams. Very sweet scented, and worth growing for that alone.

Lady Mond (H.T., William Paul and Son).—Semi-single bright red pointed buds, opening to yellowish pink. Fair growth.

Manifesto (H.T., S. McGredy and Son).—A good grower. Large blooms, shaped like Caroline Testout, flesh pink colour, with a deeper pink inside. A bedding Rose, but should be good enough for an exhibition box. Traces of mildew.

Miss Connor (H.T., Alex. Dickson and Sons).—A real protuse bloomer, with truss after truss of canary yellow coloured blooms. The buds are brighter in colour and foliage bright green. The blooms are cup shaped and not large, but would doubtless come bigger if disbudded. A splendid bedding Rose and sweetly scented.

HERBERT L. WEITERN.

(To be continued.)

THE PLANTING SEASON

PLANTING operations will be in full swing again shortly, and it has often been a source of wonderment to me why such work is not put in hand earlier than it usually is. Ground preparation takes some time, and often before the necessary trenching and formation are completed the best time for planting has passed. Many plants, and more particularly those with coarse roots, if put in at the right time will succeed, while if the time be missed they are unable to make a quick start in root action, with the inevitable result that the plant withers away and dies.

Given ripeness of wood, the early autumn in most soils is the best time to plant evergreens of all kinds. Hollies in particular can be moved without the loss of a single leaf. Yews also and, indeed, any conifer will make young roots in October, sufficient to ensure a commencement of growth in the spring, even if the weather should not be entirely favourable. Rhododendrons, *et hoc genus omne*, will go into new quarters in October without "turning a hair," as one says in the vernacular. After a wet summer, combined with an unusually low average temperature, the ripening of wood generally is at present not satisfactory, and care must be exercised not to be too soon with any plant that is not thoroughly mature. At the time of writing, however, the weather has taken a turn for the better, and a dry spell with a bit of sunshine and a drying wind will stop the flow of sap as effectively as anything.

Intending planters will have an opportunity of securing a more varied and better class of stock this coming season than for the past two or three years. Nurseries are still behind with stocks, more particularly in the purely ornamental stuff and of larger sizes, especially in properly transplanted condition; but if care is used in selection a good general all-round lot of plants is available, and now that there are signs of improvement in trade, and presumably there is some amelioration if one can believe the papers, it is to be hoped that the purely ornamental side of planting may commence again in real earnest. There may be in the present planting season a greater demand than can be filled for the best quality of stock, and that to my mind is another most excellent reason for getting well ahead with prospective work.

Ground preparation should be very thorough. It is no good doing any job in a half-hearted fashion, and this applies to planting as much as to anything. Dung or other manurial dressing must be used with discrimination. Some plants, such as Yews and Hollies, revel in coarse feeding, while others would be killed with the same treatment.

Generally speaking, if it is desirable to feed comiferous plants, it is best to mulch on the surface after the trees are well established, with ordinary stable or cow manure well rotted. I think better results are obtained by thorough preparation of the soil in regard to breaking up and trenching than by the use of artificial stimulants. Most trees and shrubs will grow well on ground thoroughly cultivated, and failure can very often be traced to the want of proper care to this end.

Planting itself must be done carefully, and one should ensure that the roots of plants when placed in position have room for proper expansion. If the hole in which a plant is put is too small, the roots are thereby restricted and cramped. The depth at which plants should be put in is also important. If too deep, root action is very slow, and in many cases I have found trees and shrubs planted so deeply that no fresh root was apparent even twelve months after. If too

shallow, the young fibres become exposed to sun and wind and are withered up as soon as they appear. Great care should be exercised to see that all trees and shrubs are firmly trodden, and in the case of larger shrubs and all trees staking is advisable to ensure immobility.

The selection of suitable shrubs is of the greatest importance. The choice is dependent in a large measure on the soil. In the case of heavy loam or clay, although there are many things perfectly at home in such soils, plants of the Heath family, including Azaleas, Rhododendrons, Kalmias and so on, do not succeed unless considerable additions of peat or leaf-mould and fibrous material are made. Again, on chalk or limestone the whole of this family should be discarded and only such plants as are truly at home on this formation should be used. The variety is limited, but good effects can be made even with limitations when the planting scheme embraces what is likely to succeed. On lighter soils, either loamy or of a peaty nature, Rhododendrons and their family

generally can, and should be, used extensively, and fortunately such soils will carry an infinite variety of trees and shrubs as well.

I think it best for intending planters who are not specialists to ask advice of any of the leading nurserymen, giving an idea of what effect is required, the space to be filled, and, most particularly, the class of soil that has to be dealt with. It is not always easy to advise by letter, and if anything like extensive planting is contemplated it is always worth while to get the advice on the spot. The best nurserymen can be said to be good planters, and it is always to their credit to have successful planting, and none, as far as I am aware, is adverse to receiving an advertisement by recommendation, which is almost certain to follow good work.

A good start is half the battle. If you are going to plant, make up your mind to do it well. If you cannot afford a lot, be satisfied with a few; but always endeavour to plant the best kinds, and the best in quality as well. One really healthy, well doing plant is worth many in bad condition, and once "bad condition" prevails in a garden it is difficult to stamp it out. F. GOMER WATERER.

THE HARDIER YUCCAS

SEVERAL of the Yuccas are hardy enough for all practical gardening purposes in most parts of this country, and considering how easy they are to grow, it is surprising that more use is not made

of them, for they are wonderfully handsome both in flower and out of flower. The best species for English gardens are *Y. filamentosa* and *Y. gloriosa* and the closely related *recurvifolia*.

Yucca gloriosa, the true type plant, is to my mind the handsomest. It forms in time a thick trunk several feet high. There used to be ancient specimens at Sutton Place taller than a tall man. The leaves are quite rigid and straight, and each is tipped with a terrible needle point. For this reason it is rather dangerous to plant it in such exposed isolated positions that folk might walk into it in the dark or where romping children might collide with it. In the variety *recurvifolia* the leaves take a slightly pendulous curve. To some minds this adds grace and beauty to the plant. Personally, I prefer the magnificent uncompromising rigidity of the type. *Y. gloriosa* may be used with splendid effect in association with rather formal architectural features, and it is also effective for growing with such sub-tropical plants as the hardy *Draecena*, Red Hot Pokers, Eucalyptus, Antholyza and so forth.

Yucca filamentosa, if less magnificent than *gloriosa*, is none the less a very fine plant. If anything it is hardier, and certainly it flowers very much more freely. An established clump of *Y. filamentosa* happily placed may be relied upon

A QUIANT GROUPING.

to flower pretty well every summer. The plant does not form such a pronounced trunk as *gloriosa*, but it makes up for this by producing numerous offsets and more quickly forming a spreading clump. All the *Yuccas* should be given a warm sunny position, a light rich soil, and if possible a raised position. In a rock garden which does not pretend to be alpine—how few do nowadays—they may be used with splendid effect. I have never seen them growing wild, nor do I know what positions they affect in the wild state, but from the way they thrive among rocks in captivity, and from the way *filamentosa*, especially, looks happy and well when placed in a setting of simply arranged rocks, I have a suspicion that such is the sort of place one would find them in at home.

The specimen in the illustration, mainly *Y. recurvifolia* with *filamentosa* behind, has been established on a little rocky knoll in very light

soil for some eight or ten years. It seldom fails to flower and this year the flower spike reached over 8ft. above ground level. In the foreground is a grove of aged specimens of that best of all dwarf conifers, *Juniperus hibernica compressa*, and in the centre of this impressive and very suggestive piece of grouping an early marble Buddha broods inscrutably over the scene. This little garden picture was not deliberately planned. Its features drifted together from time to time under the tactful whim of its owner. From a strictly critical point of view it is, I suppose, all wrong. Buddha should have had an Indian setting, and the *Yucca* comes from North America. The *Juniper*'s name suggests Irish origin, while the stream of rounded pebbles may quite well have come from Brighton beach. Yet whenever I visit this garden it is a pleasure to look at that queer individual little piece of grouping.

Stevenage.

CLARENCE ELLIOTT.

SOME THOUGHTS ON ROCK GARDEN PRACTICE

THE rock garden of to-day has slowly, if surely, evolved from the rockery which was so objectionable a feature of "villa" gardens fifty years ago. The main essential of the present-day rock garden is that it should suit its environment. For this reason it takes, in different gardens, widely different forms. There is, for example, the rock garden built against a cliff or steep bank. Broken up and diversified as such a garden may be, it will remain none the less a stone-dressed bank. Again, there is the garden formed in a natural or artificial fissure—perhaps the most natural and easily constructed of all—and the garden built in a disused quarry or gravel pit which is of the type first mentioned multiplied by four with some additional work in the enclosed space. Beyond and to some extent apart from all these is the rock garden in a slight depression or concavity, often artificially formed and consisting for the most part of turf, but with ledges of rock and suitable planting apparently scattered at haphazard but yet assembled with a master's hand to give the maximum of pictorial effect. Quite distinct, again, is the "moorland" type of garden so well exhibited by Mr. John Wood and others at the annual Chelsea Shows.

Now these few notes are not written to discuss the merits of the various styles, except that it is well to mention that the moorland effect, though beautiful in itself, is not calculated happily to accommodate a collection of choice alpinists. The few notes are written by one who has to some extent bought his experience to suggest a few considerations which should be taken into account when laying out a new rock garden. To avoid the drip of trees is a commonplace, but one that will bear repetition. The shade of trees, if not heavy and if, cast from the east, is beneficial rather than otherwise. It gives spring frosts a chance to dissipate before the sun's rays strike upon and damage delicate blossoms, and the trees themselves help to keep at bay those shrivelling winds which dry up the tissues of the hardiest plants and play sad havoc with alpinists coming from a climate where the air (as they meet it) is always charged with moisture.

A point, too, often overlooked in the search for a suitable location is the general lie of the garden. For practical as well as aesthetic reasons a rock garden should be much longer than wide, and the general direction of its length should be

north and south, so that by far the majority of aspects provided will be more or less east or west. South-east or south-west will suit encrusted and

Anemone nemorosa. Of these last the most beautiful variety is probably the jewel-like *Robinsoniana*, but the pure white wilding as generally seen is choice enough for any rock garden.

The writer has in mind an accidental planting which has given an immense amount of pleasure. A number of varieties of hardy Heaths were grouped more or less naturally in front of heavier planting. The Heaths were in groups of a kind, but not as boldly grouped as they would be were the writer carrying out the work now. Rough leaf-mould was collected for them from a neighbouring wood containing Bluebell bulbs and the twig-like rhizomes of Wood Anemones. Both Bluebells and Anemones established themselves, and very pretty they were among the Heaths, but as the background (mainly Rose species with some trees of *Acer Schwedleri*) threw heavier shade, the Heaths became more straggly and at length were rooted out. Now after a number of years the shade is quite heavy, but each spring brings the myriad silver chalices of the Anemone with their gilded interiors followed after a short interval by the glorious blue of our native *Scilla*. No picture in that garden is more valued—and the garden is of some size and contains many rare plants and, more important, many pictures—than either of the two mentioned.

Planting in the rock garden is still not boldly enough conceived. One still sees *Ranunculus*

A GEM FOR THE SHADY ROCK GARDEN, THE BLUSH PINK *SHORTIA UNIFLORA*.

tufted Saxifrages, alpine Phloxes, Aubrietias and the generality of alpine plants, whether bright but common or jewel-like and rare. Exposures practically due east or west will suit Mossy Saxifrages and a host of other plants to which excess of sunlight is detrimental. Northern, north-eastern and north-western aspects will accommodate the *Ranunculus* and *Haberleas* (planted sideways in almost perpendicular cliffs), hardy *Cyclamens*, Dog's Tooth Violets (both the European form, which is properly so called, and the American *Erythronium* now grouped with them), the *Hepaticas*, including the similar but larger *Anemone angulosa* and Wood Anemones,

in clumps of one and two. In their homeland (the Pyrenees) these beautiful plants form dense mats on the north side of wet rocks, usually under the shade of trees. If they are worth growing at all, they are surely worth growing to produce this effect. So with the *Erythroniums*. In their homelands these are carpeting plants. Effective as is a clump of, say, half a dozen, a much freer grouping is more than proportionately effective. As the bulbs of some species and varieties are rather scarce, it is fortunate that, once established, they increase themselves freely from self-sown seed, always, of course, provided that the lady of the house does not cut the blossoms.

A HALL OF ROSES

Being Notes on the National Rose Society's Great Autumn Show.

THE National Rose Society is faced with a serious problem. It was abundantly, and we may add uncomfortably, clear on September 21 that the hall at Vincent Square is quite inadequate for the needs of their Autumn Rose Show. This is one of the penalties of the Society's great and increasing success. The difficulty is to discover a hall which is at one and the same time suitable for displaying the enormous quantities of glorious Roses the members grow and show and of providing means for a great concourse to view them. Very large halls are to be had in and around the metropolis, but these are too large and they are otherwise not quite suitable. What is required is a large

every way, a great Show, a Show which no other country could equal. There were countless numbers of most beautiful Roses and these were displayed in almost every possible way, so that the visitor who did not go away satisfied, so far as the Roses were concerned must, indeed, be difficult to please. The only criticism we are inclined to offer with regard to the arrangement of the exhibits, is in connexion with the great trade displays. This is that there seems just a possibility of the exhibitors becoming stereotyped in their methods. It may, perhaps, be due to the exigencies of space, but we remember that the same thing obtained at the great Summer Show in Regent's Park. We have no doubt that many visitors would like to see some

the way orders come. We feel that the object would be attained, even in a greater degree, were it possible to display the collections more naturally.

However, the magnificent groups of cut Roses were worthy of unstinted admiration and the flower-loving public owe an immense debt of gratitude to the trade for making such gorgeous displays.

These great representative groups of cut Roses were decidedly the feature of the Show, and the first prize in the largest class fell to Mr. Elisha J. Hicks for a superb collection. His arches of such varieties as Joanna Bridge and Ophelia were very fascinating, as also were the generous stands of the fragrant Hoosier Beauty, Golden Ophelia, Climbing Lady Hillingdon and many other sorts. In their second prize group Messrs. Bees, Limited, had a great display of the showy Independence Day and the delightful single Isobel, a variety which might well be termed the Rose of the Show, for it was to be seen in great beauty a number of times. The brilliant colour of the Queen Alexandra Rose was freely commented upon in this collection. In their third prize exhibit Messrs. Chaplin Brothers had tall stands of splendid blooms of Golden Emblem, Lady Pirrie, Isobel and Red Letter Day. Messrs. Waterer, Sons and Crisp were fourth with a very creditable display. The beautiful white single Innocence was to be seen in superb form. An extra prize was awarded to Messrs. Alex. Dickson and Sons. In these groups there were also many very beautiful Roses, especially the vases of such recent novelties as Betty Uprichard, Lady Inchiquin and Mrs. Henry Morse.

In the smaller, but still large groups, the same high standard was maintained. Mr. George Prince was first with a charming display in which he disposed very artistically vases of such sorts as Padre, Isobel, Souvenir de Claudius Pernet and Golden Ophelia. Messrs. A. J. and J. Allen, who were second, included Isobel, Los Angeles and Lady Pirrie, but this collection was not so fully representative as the others. Messrs. S. McGredy and Sons were third and Mr. T. B. Edward was awarded a fourth prize.

The Exhibition Roses on boards were of decidedly better quality than might have been expected, in view of the cold, wet weather of late. But it was chiefly in the classes for Teas and Noisette Roses that any signs of weather stained petals were to be seen. In the large class for twenty-four distinct varieties the competition was very keen. Messrs. Alex. Dickson and Sons, carried off chief honours with an enviable collection which included in Annie Crawford, the silver medal bloom of the Open classes, Mrs. C. Lamplough, Edgar M. Burnett, Nelly Bligh, Florence Forrestier, Edward Bohane and Margaret M. Bulkeley, were also admirable. Messrs. Hugh Dickson were second and their best blooms were Earl Haig, Hugh Dickson, George Dickson, Caroline Testout and Alex. Emshe. Messrs. B. R. Cant and Sons were third.

The eighteen distinct varieties which won first prize for Mr. George Prince were also admirable in every way. The very best were Earl Haig, George Dickson and Augustus Hartmann. Mr. Geo. W. Burch was second. Mr. Prince was also the most successful exhibitor of twelve varieties of Tea and Noisette Roses, where he staged Lady Plymouth and Mme. C. Soupert.

The baskets of Roses are always a great feature of the Rose Shows, and the present occasion was no exception to the rule. The best three baskets

WONDERFULLY FRAGRANT, ROSE ARTHUR COOK.

but not too large hall with good lighting. The discovery of this is, of course, the National Rose Society's problem. Our present concern is to do justice to the magnificent show of autumn Roses in the limited space at disposal.

Several enthusiastic supporters of the N.R.S., and whose opinions carry great weight in the horticultural world, remarked to us that the Show under notice was quite the most of autumn Roses, and after dispassionately reviewing its predecessors, we are in full agreement with this. It was, in

attempt, at least, to depict the rose garden of our dreams—the rose garden which we all hope, but do not expect, to see. It is a garden of Roses which is at once elegant and beautiful and harmonious, a garden where the colours blend so perfectly that it would almost be sacrilege to cut even one single bloom, yet would tempt one irresistibly. We are fully aware that the nurseryman's object is to display his Roses so that they at once catch the visitor's eye, compel admiration and stimulate his desire for possession. This is

of exhibition varieties by Messrs. Hugh Dickson, Limited, were splendid masses of W. C. Wallace, Marjorie M. Bulkeley and Gorgeous. Messrs. S. McGredy and Son were a good second and their basket of Una Wallace was superb. Messrs. Chaplin Brothers have been consistently successful of late with baskets of Decorative Roses and their first prize five baskets were very beautiful. Messrs. Alex. Dickson and Sons were second and later in the day their baskets of Mrs. Wemyss Quinn, K. of K., Lady Inchiquin and Betty Uprichard were magnificent. Mr. G. Lilley's three baskets were Miss May Marriott, Mme. Abel Chatenay and Ophelia, while the three best baskets of Dwarf Polyanthas were of Orleans, Nurse Cavell and Coral Cluster shown by Mr. George Prince.

The twenty-four vases of Decorative Roses were highly creditable. Mr. G. Mattock was first, shewing Hadley, Isobel, Padre, Golden Emblem and other sorts. Messrs. F. Cant and Co., who were second, had splendid vases of Los Angeles, Red Cross and Golden Emblem. In the class for twelve vases, Messrs. Chaplin Brothers excelled with such sorts as Lady Pirrie, K. of K., Ophelia and Padre. In the second prize stand by Messrs. F. Spooner and Sons, there were glowing vases of Flame of Fire and K. of K.

NEW ROSES.

Florence L. Izzard.—This Hybrid Tea Rose had a certificate of merit at the autumn show last year, when it was called Florence M. Izzard. It now received the highest award. It is of medium size, and its rich yellow colouring makes it eminently suitable for massing. The buds and half-opened flowers are very pretty, but the fully expanded blooms are not so good. The deep green, shining foliage suggests Pernetiana parentage. This exceptionally promising Rose was illustrated in THE GARDEN, for October 2, 1921. Gold medal to Messrs. S. McGredy and Sons.

Arthur Cook.—A deliciously fragrant, fully double Hybrid Tea Rose of rich velvety crimson colouring that occasionally takes on a purple tone. It is of medium size, very shapely in the bud, and of rather flattish shape when fully open. The foliage is clean and good. Certificate of merit to Messrs. S. McGredy and Sons.

Mrs. G. Heath.—Although recommended for various purposes, this is essentially a garden Rose. It suggests Independence Day in form and habit and, like that variety, appears to be exceptionally free flowering. It is heavily shaded with apricot, and when fully open becomes a beautiful soft yellow shade. Certificate of merit to Messrs. S. McGredy and Sons.

Nur Mahal.—A Hybrid Musk Rose of most fascinating fragrance. Its habit is described as a spreading bush, and it is evidently very free flowering, as there were plenty of semi-double flowers on the branching sprays. The blooms are about 3ins. across, of rosy crimson colour, with a small cluster of bright golden stamens surrounded by an irregular, narrow, white zone. Certificate of merit to the Rev. J. H. Pemberton.

Westfield Star.—A fully double Hybrid Tea Rose of medium size and described as a Polyantha seedling. It is recommended for bedding and for forcing. It is of milk white colour with pale yellow in the heart. The flowers are very shapely and apparently are freely produced. Certificate of merit to Messrs. Henry Morse and Sons.

Vesuvius.—In form this single Hybrid Tea Rose was decidedly the most uncommon novelty of the year, and no doubt suggested the name. It may be described as being vase or goblet shaped, just over 2ins. across, with the edges of the petals

ROSE INNOCENCE IN EXCELLENT FORM.

NEW HYBRID MUSK NUR MAHAL.

THE DEEP CRIMSON VESUVIUS.

recurred and of bright velvety crimson colour. It seems to be very free flowering. Certificate of merit to Messrs. S. McGredy and Sons.

Besides the above, which received awards, there were others of more than average merit. Messrs. Bees, Limited, again brought up their charming variety Ariel, and the dark variety Macbeth of pleasing fragrance; Firefly, a bright velvety crimson Hybrid Tea Rose of flattish shape; and Sybil, which is of Mme. Butterfly type. The Adjutant, a fragrant Rose which has often been seen during the past summer, was shewn. Messrs. B. R. Cant and Sons had a stand of Sovereign, a rich yellow variety which received a certificate of merit at the summer show, but it was not in sufficiently good condition to warrant the higher award. Climbing Mme. Edouard Herriot, raised by Ketten Frères of Luxembourg is not, as shewn, equal to the bush form. The flowers were poor in colour and shape. Messrs. S. McGredy and Sons had, in addition to those that received awards, three good varieties. Herald is a deliciously fragrant deep velvety claret-maroon Hybrid Tea Rose. The colour may be a trifle difficult, but if only for its fragrance Herald is well worth growing, and it is very shapely in the bud and when half-opened. Doris Trayler is a showy orange yellow shaded Hybrid Tea Rose which when fully expanded is pale golden. Albert E. Amos is a very fragrant H.T. variety of smoky crimson colour, but somewhat lacking in form.

THE AMATEURS' CLASSES.

While the exhibition blooms in this section were not quite equal to those in the Open classes, many reached a high standard of excellence. Mr. G. Speight, Market Harborough, who was first with twelve distinct varieties, shewed fine blooms of George Dickson, which was the silver medal bloom of the section, E. Benett and Mrs. C. Lamplough. Mr. F. H. Fieldgate, Colchester, was a very good second, and was first with nine distinct blooms, where he had beautiful examples of Colcestrie, Augustus Hartmann and Florence Forrestier. R. de V. Pryor, Hitchin, shewed the best six distinct varieties and Mr. J. T. Owen was the most successful exhibitor in the class for growers within ten miles of Charing Cross. Tea Roses were well shewn by Mr. W. G. Bambridge.

The Decorative Roses were very popular with exhibitors and the judges must have experienced considerable difficulty in making the awards, though Mr. G. A. Hammond had a very beautiful collection of Golden Emblem, Irish Fireflame, Mrs. Redford and similar varieties. Mr. A. Epiffeth, Finchley, had a beautiful basket of Ophelia.

In the Artistic Sections the competition was equally good. As a Rose for dinner-table decoration it was decidedly the day of Mme. Butterfly, as this variety was used both by Mrs. A. Bire and Mrs. Courtney Page, who won the two first prizes and both were exceedingly artistic arrangements. In the amateurs' class Mrs. Oakley Fisher had a brilliant table of Isobel and, although unplaced, Mrs. Barton just missed having a very charming table of Emma Wright and Mrs. Oakley Fisher Roses. The disposition and blending of these two Roses were admirable, but the growths of Rosa sericea pteracantha, though very beautiful in their rich colour, were too stiff and overpowering.

The many bowls of Roses were a pleasant feature and Mrs. May in the Open classes and Mrs. C. Geldens and Miss James are to be congratulated on the taste they displayed, while Mrs. Charlton had a beautiful vase of Mme. Butterfly.

DAHLIAS AND HARDY FLOWERS AT VINCENT SQUARE

WHILE many gardeners in the Home Counties have had their Dahlias blackened by recent frosts, it was evident from the display at Vincent Square on September 19th that this experience is not general throughout the country. There were gold medal collections by Mr. H. J. Jones and Messrs. Dobie and Co., and both exhibitors, in quite distinct styles, had very attractive displays. Although

quite a number of people admire the regularity of the exhibition Cactus varieties, it was abundantly clear from the visitors on the present occasion as well as at the recent show of the National Dahlia Society that the popular taste lies much more towards the Decorative types, which bear plenty of flowers on stout stems sufficiently large to carry the blooms well above the foliage and, what is even more important, of a length which permit their being arranged in vases. In this respect it

A NEW CAMPANULACEOUS PLANT, CODONOPSIS TIBETICA.

THE GLORIOUS SOFT BLUE TRUMPETS OF GENTIANA FARRERI.

was interesting to find that the whole of the flowers in Mr. Jones' large exhibit were free from any support. The many Collarlette varieties, which predominated in the Edinburgh exhibit, were also self-supporting.

The small Decorative and Paeony-flowered blooms in the collections by Mr. J. T. West and Messrs. Burrell and Co. were especially graceful and of beautiful colour tones, while the dainty Pompons and the beautifully regular Singles were particularly well represented in the exhibit by Messrs. J. Cheal and Sons, who also had many vases of the popular Star Dahlias.

Of the general floral exhibits a deal of interest was centred in the large collection of China Asters which Messrs. Sutton and Sons set up. This was quite an imposing display, and shewed what a number of different types of Asters we may choose from. The sinensis varieties are particularly elegant, while for depth of colour it was such double-flowered varieties as Scarlet Mammoth and Blood Red that took the eye.

The brilliant Kniphofias were displayed by several firms, though the finest were in a collection of border plants by Mr. G. W. Miller, who had splendid spikes of Lord Roberts, cambridgensis and nobilis, and also the queer greenish-yellow Star of Baden-Baden. The hybrid Lobelias which Messrs. B. Ladhams, Limited, have shewn on several recent occasions, again found many admirers. The tall stems of such sorts as carmineus, a delightful shade of pink; Princess, rosy pink; Shirley Beauty, rich mulberry crimson; and Salmonea, clear salmon pink, to name only a few, are very valuable, especially as they continue in flower for such a long time.

Michaelmas Daisies were also of considerable attraction. Mr. Ernest Ballard had a collection of his novelties which fascinated many visitors. Little Boy Blue is a very dwarf variety that becomes smothered with semi-double dark blue flowers. Aunty Ballard, which received an award of merit after trial at Wisley two years ago, is a beautiful soft shade of blue. Bee's Pink is the pinkest of the early pink coloured sorts. Very good pink colour was also provided by the flowers of the hybrid Cordebelgi, which, as its name suggests, was raised from Asters cordifolius and Novi-Belgii. Messrs. Isaac House and Son continue to shew large quantities of their graceful Scabiosa caucasica varieties. Mr. W. Wells, in addition to a new Gentian, had some good pans of Gentiana Farreri, and he also had many border flowers. Some immense Minulus in beautiful colours, and an admirable strain of Antirrhinums, were staged by the Chalk Hill Nursery Company.

Shrubs were not very numerous, but Messrs. L. K. Russell, Limited, had a good collection of Clematis flowering in quite small pots, and Messrs. J. Cheal and Sons shewed fruiting and flowering shrubs. Indigofera decora, Colvolvulus Cneorum and Daboecia polifolia were very pretty.

Greenhouse Carnations are always in season, and besides a good collection Messrs. Allwood Brothers had many plants of their useful Dianthus Allwoodii. Mr. C. Engelmann and Messrs. Stuart Low and Co. also shewed good blooms of Carnations. Messrs. Blackmore and Langdon arranged single blooms of their magnificent tuberous rooted Begonias.

In the Annexe Messrs. T. Rivers and Son arranged a collection of splendid pot Plums. The standard trees were all heavily laden with large fruits which bore a beautiful bloom. The chief varieties were Coe's Golden Drop, Coe's Violet, River's Late Orange and President. A goodly collection of Apples and Pears was staged by Messrs. D. Prior and Son of Rose fame. Among the Apples were Worcester Pearmain, Cox's Orange, Duchess's Favourite and Peasgood's Nonsuch; while the

ripe Pears included excellent dishes of Souvenir de Congrès, Williams's Bon Chrétien and Marguerite Marillat.

The only exhibit of vegetables was a really praiseworthy collection of nearly all seasonable kinds with saladings from the Church Army Garden. These vegetables were grown on a piece of ground adjoining Vauxhall Bridge Road, not far from the hall.

NEW AND RARE PLANTS.

Aster Queen of Colwall.

—This is one of the largest Michaelmas Daisies in cultivation. The semi-double flowers have plenty of narrow lavender blue florets set on long, straight, slender stems, so that, in addition to being very effective in the garden it is eminently adapted for house decoration. Award of merit to Mr. Ernest Ballard.

Begonia Boundii.

—This is a very uncommon Begonia, somewhat of *B. gracilis* (syn. *B. Martiana*) habit, but the glossy half-heart-shaped leaves are perfectly glabrous. The fleshy stems become 2ft. and more in height. They have smaller leaves freely scattered along them, and in the axils of these are set somewhat chalice-shaped, soft pink flowers about 1½ ins. across. It might almost be named the Balsam Begonia, as the flower stems suggest a Balsam. Mr. Bound told us the plants have white tubers, and while he had had it in his possession for ten years he could not state its origin. Shewn by Messrs. W. P. Bound and Son.

Calluna vulgaris fl. pl.

A compact, free-flowering little bush bearing double flowers of a darker shade of pink than usual was shewn by Messrs. T. R. Hayes, Limited.

Codonopsis tibetica.—The plant which was on show had borne several of the interesting campanula-like flowers, but only three were open. It is a slender climber, and the sky blue five-petalled flower is lined with a deeper tone. An accompanying note stated that it was raised from seed collected by Mr. G. Forrest, and that the plant had stood out of doors last winter. Award of merit to Mr. A. K. Bulley.

Gentiana Kurroo.—A handsome Himalayan species which was introduced in 1870. It forms a neat rosette of coriaceous oblong-linear leaves, and the long-tubed azure blue flowers are borne on semi-prostate stems. Award of merit to Mr. W. Wells.

Pyrus Malus transitoria.—One of Wilson's introductions. It appears to form a slender, graceful little tree. The irregularly serrated leaves are only a couple of inches or so long, and there are small, roundish, shining red fruits. Shewn by Mr. C. J. Lucas.

Rhus Cotinus atropurpurea.—The young leaves of this purple Venetian Sumach are of a bright

shade of colour which becomes deeper with age. It is quite a decorative variety. Shewn by Messrs. J. Cheal and Sons.

NEW DAHLIAS.

The Joint Dahlia Committee had a great many new varieties before them, and they

ASTER QUEEN OF COLWALL.
With a flower of the large *A. Amellus King George* to shew comparative size.

selected the following sorts for trial at Wisley next year.

Cameo.—A large yellow Collarette of yellow colour flushed with carmine in the middle of the petals.

Cavalier.—A large Decorative variety of dull crimson colour tipped with white.

Doris Tisdale.—This is an exhibition Cactus Dahlia with broad recurved petals. The yellow colour is heavily stippled with dull rose.

Primrose.—A primrose yellow Collarette with nearly white quills. The above were shewn by Messrs. J. Stredwick and Son.

Betty.—A delightful miniature Peony-flowered variety of lilac shades.

Leonie.—The mauve colour of this miniature Peony-flowered bloom is heavily stippled with carmine except at the tips.

Peach.—A silvery mauve miniature Peony-flowered variety lightly edged with carmine.

Princess.—A golden buff miniature Peony-flowered variety flushed with rose pink, especially on the outer half of the petals.

Raider.—A miniature Decorative bloom of soft terra-cotta shade with a suggestion of purple in the centre.

Tipsy.—Another miniature Decorative bloom of rich scarlet colour rather darker in the centre. This and the five previous varieties were shewn by Messrs. J. Burrell and Co.

Crawley Beauty.—A Parisian single of large size and velvety maroon colour edged with crimson.

Lady Hurst.—A bright rosy mauve Star Dahlia which has a yellow centre.

Mrs. Trist.—A compact Camellia-flowered variety of purplish magenta tone.

Peggy Lobjoit.—The colour of this Star Dahlia is a light rosy mauve, and there is a little yellow in the centre of the flowers.

Rowett Star.—A very uncommon variety of yellow colour shaded with light purple on the outer half. This and the four above were shewn by Messrs. J. Cheal and Sons.

Dainty.—A charming Star Dahlia with a yellow centre and flushed with mauve. This and the following were shewn by Mr. Charles Turner.

Sweet Dorothy.—A bright mauve Star Dahlia which has a paler zone.

Snowdrift.—A very good miniature Cactus Dahlia of milk white colour.

NEW CHRYSANTHEMUMS.

At their first meeting of the season the Floral Committee of the National Chrysanthemum Society re-elected Mr. D. B. Crane as chairman for the twentieth time and considered the merits of a great many novelties. The following varieties were the most promising.

Cissbury White.—This is a very useful incurved sport from the reflexed variety Framfield White. It produces plenty of compact blooms about 3½ ins. across. The pure white of the mature florets is relieved by the suggestion of yellow in the centre of the flower. First-class certificate to Mr. M. Aish.

Framfield Early Yellow.—Another sport from Framfield White, but in this case the habit more nearly approximates the type and as the colour is a pleasing shade of yellow it will be valued as an early Chrysanthemum. Shewn by Mr. J. Emberson.

Lichfield Early White.—This white seedling was raised from Sanctity and Miss G. K. Thorpe. It is a medium-sized Japanese bloom of graceful form. The centre of the bloom is greenish yellow. First-class certificate.

Mrs. A. W. Thorpe.—The colour of this graceful Japanese variety is a delightful warm shade of buff terra-cotta. Both naturally grown and dis-budded blooms were shewn and they are equally attractive. The flowers are of medium size and made up of narrow slightly drooping florets. First-class certificate.

Ray of Hope.—A small single-flowered variety suitable for growing as sprays. It is a seedling from Shrapnel and of warm orange yellow colour. There is a slight rosy zone to the flowers. This and the two varieties named above were shewn by Mr. M. Thorpe.

September Gem.—Although this rather more than medium-sized rich yellow single did not find favour with the committee, it has all the appearance of being a highly decorative variety for the garden and for decoration. Shewn by Messrs. Wells.

Waterwitch.—This dainty little pure white single was decidedly worthy of a better fate than being "passed." It appears to be exceptionally free-flowering and a flower that will last well in a cut state. Shewn by Mr. M. Thorpe.

FORTHCOMING EVENTS.

October 3.—Royal Horticultural Society's Great Autumn Show to be held at the Holland Park Rink (four days).

October 4.—United Horticultural Benefit and Provident Society's Annual Dinner to be held at the Imperial Hotel, Russell Square, London.

SHADY BORDERS

Their Planning and Planting.

THE shady border is perhaps the most difficult problem with which the suburban gardener has to deal, and really calls for a great deal more consideration than it usually gets from even the very best gardening books and newspapers. Queries are too often answered by the suggestion that it is

to 3ft., will be desirable, but generally speaking it will be found sufficient thoroughly to trench the ground to that depth, incorporating with it plenty of leaf-mould, road scrapings, and well decayed manure; anything, in fact, that will lighten it if heavy and help to give it consistency if over-light. In most cases a dressing of lime will be very

ADMIRABLE FOR THE SHADY BORDER, LILIUM MARTAGON ALBUM.

just the place for Ferns, and that the Japanese Anemone does not mind shade if it is not under the drip of trees. In large gardens it is, of course, often possible to lay out the ground so that the shady border is not much in evidence; but in the comparatively small suburban garden it is almost sure to be there and in full view from the windows of the house. The plot has probably a little piece of grass in the centre which gives a sufficiency of green, and most people would like to have something bright to look upon on either side and at the end, and incidentally to hide the palings or the bare wall which divides their plot from their neighbours. Numbers of plans have been drawn out by skilful garden artists shewing delightful variations of this simple scheme, yet it is still the most common, and few succeed in eliminating the shady border altogether.

In dealing with the problem the first point for consideration is whether the shade is open, or the site overhung by trees. In the former case there are many plants which should succeed perfectly well, but in the latter the number is greatly restricted. It will, therefore, perhaps be simpler to deal first with the border in open shade.

The first, and really after all the chief, consideration is to prepare the soil properly; many of the failures which occur must be attributed entirely to neglect of this matter. Soil which does not get much sun tends to get sour more quickly than that in a sunny situation, and extra attention to drainage will be necessary. In some cases a 6in. layer of stones and brickbats, placed at a depth of 2½ft.

beneficial, but this must be omitted if the space is to be planted with Rhododendrons, Azaleas or other lime-hating plants. Any good soil there is should be kept fairly well to the surface. If good turf loam is available it will be appreciated by everything. A sharp look-out should be kept for snails and slugs, which rejoice in damp and shaded spots, and a good soil fumigant could be employed with great advantage.

Should the border be very narrow, as it often is, it will generally be found a great improvement to widen it considerably; to a minimum of, say, 4ft. The amateur gardener often does not care to do this as he fears that it may merely increase the area of unsuccessful gardening, while taking away from the lawn which is, it may be, in a thriving condition. Yet the increase in width will greatly increase the probability of success since it will give room for the majority of the plants to be placed further away from the fence, thereby probably ensuring them a little sunshine in the summer, and also giving them a considerably larger space of good soil to draw upon for nourishment. In any case provide, as far as possible, against draughts.

Having thoroughly prepared the soil, the next point is to plant something to cover the wall or palings as quickly as may be if they are objected to as a background, which will almost certainly be the case. The choice will be quite limited, since these plants must be placed fairly close to the fence and consequently in a deeply shaded spot: in fact it will probably be best to plant it entirely with Yellow Jasmine (*Jasminum nudiflorum*), as that is

one of the very few things which will flower satisfactorily in such a site, and it has moreover the merit of flowering in winter, and so making the border cheerful at the dullest time of the year. It is a pretty dark shade of green which will form a good background to almost any flower, and, although deciduous, the stems are of the same shade, and when it is well and thickly grown they give almost the same satisfactory effect. The Morello Cherry would do quite well in this position, and its beautiful flowers in spring will be followed by a crop of fine red fruit. It should be allowed to grow somewhat loosely, as Cherries do not like severe pruning.

When the background has been arranged, the following can be recommended as likely to prove thoroughly satisfactory: Snowdrops, Winter Aconites, *Scillas bifolia* and *sibirica*, for early spring, followed in mid and late spring by Daffodils in endless varieties. Oriental Poppies or *Pæonies* will make a fine show in early summer, but perhaps the *Pæonies* are most to be recommended, as their fine foliage will help to hide the decaying leaves of the bulbs, which are so difficult to arrange for. For midsummer, *Campanula lactiflora*, a tall growing perennial with lovely pale blue flowers, would be very satisfactory. It will reach a height of 4ft. or 5ft., but not in the first year after planting.

Then for late summer and early autumn, Phloxes will prove the most brilliant choice, but Michaelmas Daisies and Golden Rod will also be quite successful and give a good touch of colour. Japanese Anemones, especially the pink form, could also be added. The many people who always ask for blue flowers would perhaps prefer English Irises in the early summer, and add Monksblood in autumn; but blue really seems to want, unless of a pale shade, more sunlight it is to be seen in full beauty.

The edging will depend much upon the taste of the gardener, and is too large a subject to deal with in the course of this article, beyond recommending *Violas* and *Mimulus* as likely to be the most successful low-growing flowering plants for the situation. *Polyanthuses* would also do well, but they flower only in the spring. An entirely different treatment for the border in open shade would be to plant it chiefly with Rhododendrons or Azaleas, interspersed with various Lilies which, if well chosen, would continue the flowering season right into autumn. The bulbs recommended in the previous scheme would furnish colour in the earlier spring, and Rhododendrons *dauricum* and *microlatum* could be added. They flower in late winter, and look lovely with Snowdrops and Scillas, but then Winter Aconites should be omitted as their bright yellow colouring does not shew to best advantage against the pale magenta Rhododendrons.

The same soil would be suitable, omitting the dressing of lime. The more leaf-mould and grit the better, and a little peat, if available, would be acceptable to all. A layer of sand should be put round each Lily bulb. The Lilies may not flower very well the first season, but when well established they are admired by everyone, and this beautiful genus of plants is too much neglected in the suburban garden.

Many people do not plant Rhododendrons and Azaleas because they consider them too slow growing, but they respond wonderfully to continuous watering in summer, and will then put on new growth at least twice as long as they do when left alone. They prefer rain water, but do not seem to mind ordinary hard water, though they do not like one definitely chalky. A great deal may be done to keep them moist and in continuous growth in summer by a good mulch, and it is well to spray them as often as possible. They respond gratefully to atmospheric moisture, even if only supplied by the hose. Of course this scheme of planting would be more expensive in the first place, but it

should solve the problem for a number of years with comparatively little further outlay of money or labour. Where very good immediate effects are desired, quite large bushes may be moved, and if good varieties are chosen, especially of the late-flowering brilliant red and pink Azaleas, the effect when they are in bloom will be gorgeous.

Yet a third solution, which might appeal strongly to the more botanically minded gardener, would be to devote the open shady border to the Primula family, but that solution would require an article to itself to do it justice.

THE SHADY BORDER OVERHUNG BY TREES.

Under the drip of trees it is difficult to get many things to thrive; still, with careful cultivation, a good number may be grown. Often it is the poverty of the soil and the dryness caused by the greedy tree roots that are the chief causes of failure. Trees, especially large ones with dense foliage, quickly drain the soil of almost all moisture, and, also, as may be readily imagined, of the plant food that is in the soil. People so often put plants under trees and then leave them alone to get on as best they can; whereas they are really much more in need of care and feeding and watering than most plants in the open border.

Evergreen trees, it is true, offer an almost insoluble problem, since the few things that might be made to flourish under them are scarcely suitable for suburban gardens.

The following plants and shrubs may be relied upon in a carefully cultivated shady border, even if overhung by deciduous trees: Rhododendrons, including the early-flowering variety nobleanum; *Rubus odoratus*, a purple flowered Raspberry with very fine foliage; the Mahonia, *Berberis Aquifolium*; *Sarcococca ruscifolia*; Rose of Sharon, *Hypericum calycinum*; the Rose Bay Willow Herb, *Epilobium angustifolium*; *Lysimachia punctata*, a fine yellow flowered perennial; Solomon's Seal; the common Bluebell, *Scilla nutans*; Sweet Woodruff, *Asperula odorata*; the Winter Aconite, *Eranthis hyemalis*; and Snowdrops.

Rhododendrons really prefer shade, and often suffer from a very virulent fly when grown in full sunlight. One is often told that Snowdrops do not flourish in suburban gardens, but in most cases there would be no difficulty with them if they were helped with a little leaf-mould and a constant watch were kept for slugs. Rhododendron nobleanum flowers in February, and is very bright and cheerful to look upon in that specially dull time of the year. A. E. W.

of the wild Mallow. The word amethyst has been so often misused both in botany and horticulture to denote something of a blue colour, that it is a pleasure to see the word rightly applied. Anyone who knows or possesses amethysts would see how useful the name of the gem is for describing a certain class of colour, as may be seen in the case of these lovely flowers. In this series Remembrance is the deepest and Amethyst the lightest, being only tinged with colour, as it is in the least strongly tinted of these gems. Another range is Queen Mary, palest rosy pink; Loveliness and Délice; Délice is the deepest of the three. These have no hint of amethyst in them, but are of a clear rosy pink, charming to use together.

The yellows are truly magnificent in nearly related shades of clear and brilliant colour. Yellow Colosse has something of the old-fashioned charm of the old quilled Dahlias, but has less formality; Brentwood Yellow is a splendid flower, evidently one of the best for border planting. Yellow King, a slight shade lighter than the others, is an immense and massive bloom, 7ins. across.

Three pretty flowers of the Mignon class, also in a clear, bright yellow, are named Louise, Pembroke and Daffodil; the last, a little the deepest in colour and of firm substance. These starry yellow Dahlias group beautifully with striped Maize and with Cannas that have light green foliage and pale yellow flowers; in association with white and yellow Snapdragons, the clear yellow *Calceolaria amplexicaulis* and the ever useful variegated *Mentha rotundifolia*, a charming picture of well related colouring may be made.

COLOUR EFFECTS IN THE FLOWER GARDEN

BY GERTRUDE JEKYLL, V.M.H.

IN some arrangements for colour effect in late summer there has been a difficulty in fitting the colour required to the place and season, yet I felt sure that, with the now extensive range of garden plants, the thing wanted must surely exist. What was desired was some Dahlias of the so-called Decorative class in colourings of cool pink and bright yellow. As I am unable to visit nurseries or shows, I wrote to

Messrs. Cheal of the Nurseries, Crawley, Sussex, and am thankful for their kindness in sending me a series of superb blooms. As other readers of THE GARDEN who are keen on good colour may like to know of them, I should wish to mention the following. A beautiful series of cool pink or mauve pink is Amethyst, Silver Queen and Remembrance. These may be described as of a true amethyst colour, near akin to typical mauve, the cool pink

The Decorative Possibilities of Autumn Foliage

IN spring the young tender leaves are admired and welcomed, although some would think their beauty a trifle cold. The observer knows, moreover, that soon there will be deeper tints, maturity and fruit following flowers in many instances. In autumn the tints are warm and soothing to the eye and one wishes that they would linger on throughout winter.

In the wild woodlands the harvest of autumn tints is abundant. There are many, however, who are not able to enjoy woodland scenery, but even in the town and suburban garden some autumn colour in leaf and stem may be enjoyed if, when the work of planting is being carried out, a few small bushes or a couple of trees be included which will furnish this desired colouring in due course. *Cornus alba* (Dogwood), *Rubus biflorus* (with almost pure white stems), *Pyrus Aria majestica*, *Ivy* (under trees), *Cotoneasters*, *Berberis Aquifolium*, are a few that succeed in town gardens.

For large gardens and pleasure grounds in the country, the kinds and varieties suitable are numerous. To obtain the most desirable effect where borders or grounds are fairly extensive, there must be a judicious addition of evergreen trees and shrubs, mixed with, or affording a background to, the deciduous ones, the foliage of which contains the various colours and shades which we so much admire. Care should be taken, however, to avoid spottiness in planting.

In a garden I visited some while ago, the yellow-stemmed Willows, growing luxuriantly in moist ground near a pond, were very effective; a dell, from which the sturdy branches of Oaks and Beeches rose 30ft. to 40ft. above ground level, formed a background; nearer at hand were the terraces and less formal parts of the pleasure grounds, well furnished with groups of suitable shrubs. In many cases the tinted foliage suggested, at first glance, masses of flowers. G. G.

DECORATIVE DAHLIAS IN THE HERBACEOUS BORDER.

CORRESPONDENCE

THE YELLOW MICHAELMAS DAISY.

I AM very glad that Amos Perry got an award of merit for the novelty *Aster hybridus luteus*, a while ago. I have a couple of plants in my collection of *Asters*, and so I can say from personal experience that it is a most attractive little plant with its beautifully formed small soft yellow flowers, very near that delightful shade which the older generation of Daffodil lovers called a John Nelson or a Captain Nelson yellow. Little, of course, is only a comparative term. The newcomer is tall if measured against one of the *Amellus* section. The adjective is intended to describe it alongside a typical *Novi Belgii* or a *Novæ-Angliæ*. On decently good ground here it measures 2ft. 6ins. It was in full flower on August 30. I feel in duty bound to mention the fact that someone who evidently did not think very much of this flower placed one day among the blooms some sprays of a common wayside weed known locally by a name not suitable for polite ears to hear (but which is faithfully recorded on page 323 of that most interesting work "A Dictionary of English Plant Names," by Britten and Holland), which to the "high lan'd" is *Senecio Jacobæa*. The unwritten name is still used locally, but not in drawing-rooms. My friend has, since these words were written, seen the *Aster* in full flower and has apologised for the suggestion made by the placing of the *Senecio*.—MAELOR.

COLLETTIA SPINOSA.

I AM puzzled by the exhibition at the R.H.S. Show on September 5 of flowering sprays of *Colletia spinosa*. Here this shrub always flowers in early summer. This year it began on May 31, and is now wholly without blossom.—HERBERT MAXWELL, *Monreith*.

THE POPLAR HAWK MOTH.

EARLY in July a pair of these beautiful moths was brought me, and in a day or two many green eggs dotted the breeding-cage. On July 22 a general hatching took place, and the tiny larvae at once "got busy" on Poplar leaves. Several were placed on a tree in the garden, but they soon disappeared, possibly eaten by birds. A solitary egg was found glued firmly to a leaf. Was this a coincidence or had another moth of this species "sensed" the presence of the other larvae? They are a beautiful shade of green; the skin is rough like shagreen, and down each side is a row of seven yellow stripes. If one uses a strong magnifying glass, one can see a row of red breathing holes along the sides. At the end of the body is a yellow horn, red at the base, and the legs are pink in colour. The amount these creatures eat is astonishing. Leaves placed in the cage soon become a mass of shrivelled stalks. The magnifying glass shows you how powerful their jaws are, and when one larva gives another a nip you can see by the sudden twitch that discomfort, if not pain, is felt. Earth has been placed at the bottom of their cage, and they are now full fed and beginning to turn into pupæ. When this transformation has taken place, they will remain quiescent until the spring. The colour of the pupa is brown, and has a queer look as if it had been dipped in mud and dried. The moth emerges from the pupa-case in early summer. Its forewings are grey with a white spot in the middle, the hind-wings having a bright red-brown patch at their base. It gets its name of hawk from its peculiar darting, hovering flight, a characteristic of all the Sphingidæ, or hawk moths. The sphinx

like attitude of the larvæ is seen at once when it is touched, as its head is suddenly raised, remaining immovable till danger is past. Verily there are other things of interest in a garden besides the flowers.—D. W. D.

WHAT DOES THE PICTURE REPRESENT?

I THINK the accompanying picture of a branch of Blackthorn may interest your readers, if only as shewing what the blossom ordinarily loses for want of foliage to accompany it. In this case the dearth of foliage is largely compensated for by a wealth of Lichen which, judging by the flowering, appears to have had little detrimental effect upon the tree. The Blackthorn is effective when in flower either in the hedgerow or in thin woodland and the double form (*Prunus spinosa* fl. pl.) makes

SINGULAR "FOLIAGE."

a pretty, small tree or large shrub. There is now a pink-flowered, purple-foliaged form called var. *purpurea*, which is said to be very effective, but I am not personally acquainted with it. When heavily laden with its blue-black sloes, the typical tree is very effective in autumn, but its cropping is rather spasmodic.—S.

THE TREE CYPRESSES.

THE writer of a paper on Conifers (page 462) refers to the true Cypresses as "emphatically trees for the Midlands and the South, as even the hardest will not withstand the rigours of our Northern winters." May I point out, as has been often done before, that in Great Britain winter temperature is far more a matter of longitude than of latitude. *Cupressus macrocarpa* thrives vigorously, both as a forest tree and a hedge plant, in the maritime districts of Scotland, especially on the west coast as far north as Ross-shire. To produce clean timber (valuable because of its

durability when exposed to weather) it must be planted in close canopy. As for the Italian Cypress, *C. sempervirens*, its hardiness in our climate seems to depend in some degree on the region whence seed is obtained. In 1878 I gathered some cones at Fiesoli, near Florence, where there is considerable winter cold. The offspring of these cones now stand here, averaging 30ft. high, in perfect health. In 1907 I gathered other cones at Ragusa in Dalmatia. Seedlings raised from these were all killed by frost in the nursery. *Cupressus formosana*, recently introduced from Formosa, said to be the loftiest species of Cypress, attaining a height of 200ft., has passed through three winters here unhurt without any protection.—HERBERT MAXWELL.

[It is doubtless a pity, as Sir Herbert Maxwell suggests, that when writing of shrubs, hardy only in favoured districts, the "south" is often used without the qualifying word *inland*, but happily most readers are aware of the special conditions applying on our western seabards.—ED.]

ANTIRRHINUM PRIMA DONNA.

HAVE you ever reflected on the swing of the pendulum from the usage of old-fashioned English names to the more "starchy" Latin and Greek ones? Thus Larkspurs have become Delphiniums and Snardragons Antirrhinums! Pages and pages might be written about it. We must nowadays be so precise and correct. The sea of continually improving communication is slowly and surely wearing away the little inlets of isolated hamlets and secluded villages with their old-fashioned speech, and the coastline is becoming monotonous in its uninteresting evenness. Never mind, there are compensations. We have no end of varieties. They are as the sand on the seashore. To these we can still give English names, but it is

not quite the same thing. They are seldom "pet" names as Apple-pie and Betty-go-to-bed-at-noon were. The rolling panorama of the world of flowers moves so quickly that it is "here to-day and gone to-morrow." The pretty pink Nelrose among Antirrhinums is one exception to this rule, although it probably owes much of its comparatively long vogue to its behaviour under glass. *Prima Donna*, which came to me from Dobbie's, is worthy of a place beside Nelrose. It has a colour which is difficult to describe. The best I can do is to call it a soft rosy fawn. It is very pleasing in the open and even more so under artificial light. I always grow the medium of Antirrhinums. In doing so I do not see exactly eye to eye with Jesse Suff (I am uncertain of my spelling), a philosopher of a bricklayer who in the course of a conversation when he was helping to build my rectory convincingly remarked, "I don't like any of them mediums; *give me*, I say, beer or champagne."—JOSEPH JACOB.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

French Beans growing in frames require rather more attention from now onwards. Should the weather be cold and changeable, it will be better to keep the lights always on, even though the plants are in bearing. The extra warmth gained will greatly help the plants, though on warm days a more free airing should be given to assist in getting rid of accumulated dampness. Should the plants be growing in frames without the aid of pipe-heat, some outside covering should be given on all cold nights and thus help to conserve the existing natural warmth.

Cauliflowers.—An abundance of these have been available and, indeed, are still turning in so readily that it may be found necessary to pull some of the plants up and have them removed to a cool dark cellar, suspended in which, curds downwards, they will keep many days in excellent condition. The lesser developed heads must also be thought of and upon the threat of a cold night have a few of their leaves broken over them as these will greatly assist in warding off possible danger from frost.

The Flower Garden.

Transplanting Shrubs.—The present time is quite one of the best and often convenient, too, for carrying out this operation. An important point which should not be overlooked, more especially in cold districts and where a cold soil has to be dealt with, is that the work should be carried out as early in the autumn as possible. At this season the soil is not only in a good workable condition, but it still has a great amount of warmth left in it, and the importance of these two factors in encouraging new root action can be readily understood.

Sweet Peas.—Where the raising of these plants is done during the autumn, now is a good time to carry out the work. Seed may either be sown in 4in. or 5in. pots or in well prepared ground outdoors. On cold heavy land the latter method is hardly worth attempting, but on a warm, well drained soil there is decidedly a gain of several weeks between the autumn and spring sowings. The batch grown in pots cannot be grown too sturdily, and only during a very severe spell or a prolonged wet period is it necessary to shut the frames up. Place three, four or five seeds in pots a corresponding number of inches in diameter.

Cuttings of many evergreen shrubs made now from the well ripened wood will root readily in cold frames or even outside on warm borders. Use plenty of grit in the compost and see that the cuttings are made thoroughly firm.

The Hardy Fruit Garden.

Preparations for Planting.—A few words upon this matter have already appeared in an earlier issue, but it will now be necessary to push on with the work as quickly as possible. Fencing or clearing of the ground should be attended to at once so that the site may be somewhat settled again before planting is done. While the above operation is in hand ascertain that the position of a new one is sufficiently drained. Make use of wood-ash and any old burnt refuse to improve the soil, and also a goodly amount of old plaster rubble where stone fruits are to be grown.

Grease Banding.—Early October may be taken as a convenient time to get this work done, the object being to trap the female moth as she travels up, which, generally speaking, commences about this time.

Fruits Under Glass.

Root-Pruning Peaches.—The next six weeks is the time for dealing with any necessary root pruning, making a start now in the early house if such work be intended. It is not very often that such work is necessary upon well established trees giving good annual returns, but rather upon more recently planted trees which are inclined to be rather gross of growth. Having taken a trench out about 2ft. deep and from 2ft. to 4ft. away from the stem, according to the size of the tree, gradually work with the aid of a fork until it can be ascertained whether any strong tap roots are penetrating the subsoil, and when such are found sever cleanly through with a sharp knife. Be careful when filling the soil in again to make it very firm and encourage the lay of the roots in an upward direction as much as possible. The carrying out of this operation affords an excellent chance of adding some old

mortar rubble to the border. Give a good watering to re-settle the soil, and syringe the trees for about a fortnight should the weather be warm and dry.

H. FURNER

(Gardener to the Duke of Northumberland),
Albany Park Gardens, Guildford

FOR NORTHERN GARDENS.

The Kitchen Garden.

Beetroot.—The main crop of Beet must be accorded more care when lifting than is necessary with the early Globe varieties. Avoid bruising or breaking the roots, especially the tap roots, otherwise they will be of little use for kitchen purposes, being insipid and pale in colour when cooked. Store the roots in a cool shed in fine soil or sand, arranging them in layers. Cover over with straw during the winter.

Mushrooms.—Continue to collect horse-droppings for successional beds. Have the manure placed in an open shed where it may be frequently turned to prevent it becoming sour. Beds which were spawned a month ago should be examined and if the surface should be dry, give a gentle watering with tepid water. Syringe the walls and floor of the house regularly. On beds where the Mushrooms are showing through, covering material should be removed as the Mushrooms will be found to develop more quickly and cleanly without it.

Lifting Potatoes.—All Potatoes should be lifted at the first favourable opportunity, as owing to excessive rains during August disease is noticeable in many gardens in our western district. Where airy sheds or cellars are available for storage, they will be found most convenient, especially for looking over the tubers during the winter months, but if placed in well made clamps they will also be found to keep in excellent condition. Tubers showing the slightest trace of disease or damage should be picked out during the storing period. When arranged in position in the clamp a good supply of straw should be used as a covering, placing on top of this sufficient soil to exclude hard frost.

Celery.—Add more soil to that already put round the earliest crop and give the first moulding to later lots. Remove all suckers and decayed outside leaves and tie the stalks sufficiently firmly to keep the soil from working in and destroying the hearts. Dig up and pulverise the soil thoroughly before earthing up.

The Hardy Fruit Garden.

Planting Fruit Trees.—Although it is yet rather early to plant, notes of requirements in the way of new trees for filling vacancies caused by trees dying out or which may arise through clearing away worn-out specimens or from a desire to replace inferior kinds by those of a superior quality may be taken, and the order placed in the hands of a reliable nurseryman. Do not be led away by advertisements regarding cheap trees. In many cases this is only the cause of much worry and regret, as they cannot always be depended upon as being true to name. It is certainly more economical to pay a fair price to firms who, in working and training their young stocks, lay the foundation of a tree that at an early date will give satisfaction to the purchaser. When grubbing up old trees, care should be taken that all the old roots are removed, as when roots of any size are left in the ground there is always a risk of fungi being bred which in due course may attack the roots of any young trees that may be planted on the same site.

The Flower Garden.

Violas.—Cuttings of these should now be got in for next season's display. Choose the firm stocky growths, breaking away from the centre of the plants and dibble into a cold frame containing a mixture of leaf-mould and sand. Keep the frame close for a few days and then allow a chink of air during open weather. Viola cuttings damp off readily if the frame is kept too moist or ventilation neglected.

Bedding Calceolarias.—The first week in October is the best time to propagate these. In taking cuttings do not use growths showing a flower bud, as these are the least satisfactory. Similar frame treatment to that recommended for *Violas* suits these *Calceolarias* admirably.

Dahlias should be looked over at this time and any additional tying necessary be done. Where growth is very dense it may be thinned out with advantage to the plant and the better development of later flowers.

JAMES MCGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.,
Coodham, Kilmarnock.)

GREENHOUSE AND CONSERVATORY.

Basket Plants add greatly to the appearance of a large conservatory and there is quite a number of beautiful plants useful for this purpose.

Asparagus Sprengeri makes an excellent basket plant and plants that were raised from seed during the spring are now ready for putting into baskets. These plants have a large root system so therefore require fairly large baskets.

Asparagus scandens deflexus is another very graceful and beautiful plant for baskets and can be raised from seed in the same way as *A. Sprengeri*.

Saxifraga sarmentosa is very pretty for small baskets, and if runners are secured and potted up at this time they will be ready for transferring to baskets early in the New Year.

Convolvulus mauritanicus, although hardy in many places in the south and west, is a very beautiful basket plant for the cool greenhouse. It is easily raised from seed, which if sown about this time will make good plants for flowering next summer. It grows well in any ordinary potting compost and requires perfectly cool treatment at all times, and in a sunny greenhouse produces its beautiful blue flowers in great profusion.

Lotus Bertholetii (syn. *L. peliorhyncus*) is also an excellent plant for baskets, with fine grey foliage and brilliant scarlet beak-shaped flowers. If propagated from cuttings at this time good plants may be obtained for next summer. It is not always an easy plant to root successfully, as the cuttings are very apt to damp off. It is best rooted in a cool airy greenhouse, placing the cuttings under a bell glass, which should be carefully wiped dry every morning.

Ivy-leaved Pelargoniums are, of course, popular and well known basket plants. If good specimens are required for next summer, cuttings should be rooted at this time. A few of the best varieties for the purpose are *Mme. Crousse*, *Scarlet Crousse*, *Jean d'Arc*, *Galilee*, *Souy*, *de Charles Turner* and *Elegante*. The last named is a very pretty variegated variety. Here I may say that some of the stronger growing varieties, if planted out, are excellent for covering the back wall of sunny greenhouses.

Fuchsias are also excellent for baskets, and for this purpose preference should be given to such varieties as naturally are of the slender or drooping habit. If plants are required for early summer flowering, cuttings should be inserted now and they will make good plants for transferring to baskets early in the New Year. For late summer and autumn flowering, cuttings may be put in during January and February.

Fuchsia procumbens is a small prostrate-growing species from New Zealand and makes a very pretty picture in a small basket. It is easily propagated at any time by means of cuttings, which root readily in a close case in a cool house.

Heeria elegans is another good plant for small baskets and is easily propagated at any time by means of cuttings. If inserted at this time they should make good flowering plants for next summer.

Chlorophytum comosum, with slender variegated leaves, is an elegant plant for small baskets and is easily increased at any time by means of the young plants which are produced at the end of the runners.

Campanula isophylla, blue and white and the variety *Mayin* are beautiful for baskets, as also is *Campanula fragilis*. The examples given will serve to show that there are quite a variety of plants that can be used for this purpose; and many others will suggest themselves to the plant lover.

Darwin Tulips are increasingly popular for pot culture and as success depends very largely on their being well rooted, they should be potted up as soon as possible. They are much larger-growing than the early-flowering varieties, therefore require larger pots to grow them successfully. I find it pays to put them into 7-in. or even 8-in. pots. In such pots they make fine specimens and are useful for standing on the floor. Some five or six bulbs should be placed in a pot. After potting they should be placed outside and covered with leaf soil or finely sifted ashes. If the latter are used they should have been well exposed to the weather,

as it is never safe to use fresh ashes for this purpose. The bulbs should remain under the covering until they are well rooted and growth begins to show on the top of the pot, when they should be removed to a north frame. This class of Tulip requires much more careful management than the early-flowering varieties. They will not stand the same hard forcing, but must be brought on more gradually and cooler than the early varieties. They are so beautiful that they are worth some extra trouble.

Royal Botanic Gardens, Kew.

J. COULTS.

Vegetables all the Year Round

October Operations.

NOTWITHSTANDING the fact that we are rapidly approaching the period of comparative slackness in the vegetable garden, October must be regarded as a month of considerable importance, as well in respect of the results of the past season's cropping as of the results that it is hoped will be achieved next year. There still remains some planting which can be done advantageously, harvesting work must be carried to finality, while the desirability of coming to a decision upon future planting may well have due consideration.

GROWING CROPS.

These will comprise plants in various stages, and all will demand thoughtful attention. It is of paramount importance that the rows of winter Spinach shall be adequately thinned, since it is only those plants which complete their development under the beneficial influences of unobstructed light and fresh air that yield satisfactory returns. Therefore follow up gradual thinning until the individual plants in the lines are now less than 15 ins. asunder, and when the time comes for gathering from them do not forget that it is infinitely more profitable to take the best leaves from many plants than it is to strip one or two, as is usually done in summer. Parsley, too, should be freely thinned out.

The hoe should be used incessantly during suitable weather between these crops and also all Winter Green vegetables, as well to keep down weeds as to facilitate the admission of rain and fresh, invigorating air. It is not infrequent to find that these last-named plants grow too luxuriantly in open weather; in such event choose a time when the surface is just on the dry side and tread hard down round the stems slightly to check the root action; it is not much trouble and goes to favour a hardier plant. The latest batch of spring Cabbages and Borecoles should go to their permanent positions forthwith to give them a chance to secure a foothold at least, even though they do not make material progress until the spring. Sometimes this late planting is valueless, but there comes the occasional season when it proves absolutely invaluable. It is, then, a useful form of insurance. There is a possibility that both Celery and Leeks will demand water; if they do, see that the soaking is a generous one. Earthing of the first named crop should proceed as necessary. It will be wise to break leaves over the heads of autumn Broccoli and Cauliflowers about the middle of the month as a measure of precaution.

HARVEST WORK.

It is the custom of many growers to leave all Potatoes in the ground to ripen, and the reason given is that otherwise they will not keep. This is, of course, utterly erroneous, and the practice should fall into disuse because it is late in the season that blight is apt to secure a hold on the tubers and develop when they go to store the partial

or entire ruination of most valuable food. The one disadvantage of lifting before ripeness is that the skins rub unless they are handled with care, but even so they will keep just as long, though their appearance will be somewhat marred. Storage of "ware" tubers must be in the dark with total exclusion of frost. If seed tubers are saved at home, they should be separated when lifting is in process, and their place of storage should have full light, abundance of fresh air and entire freedom from frost.

The principal root crops to go to store are Beetroots and Carrots, and the best method is in heaps of alternate layers of soil and roots, tails inwards. Beetroot, as the more tender plant of the two, will be dealt with first. Scrupulous care must be taken not to break or bruise the roots, and the tops should be screwed off a couple of inches above the crown. Carrots may have the tops cut off close to the crown. In neither instance should all the soil be rubbed away on the score of cleanliness; a little adhering assists the keeping properties appreciably. Parsnips lose quality so quickly after lifting that it is preferable to leave them in the bed and take out sufficient for a week's requirements at a time.

W. H. LODGE.

TRIAL OF DAHLIAS AT WISLEY

THE following awards have been made to Dahlias by the Council of the Royal Horticultural Society after trial at Wisley. The Dahlia trials at Wisley were judged by the Joint Dahlia Committee, consisting of members of the R.H.S. Floral Committee and the National Dahlia Society.

EXHIBITION SINGLES.—*Awards of Merit.*—Clematis and Bishop Crossley, sent by Messrs. Treseder. *Highly Commended.*—Mamie, sent by Messrs. Cheal; Amy Barrillet, from Mr. Bowles.

MIGNON.—*Awards of Merit.*—Albion and Janet, sent by Messrs. Cheal. *Highly Commended.*—Kathleen and Mincio, sent by Messrs. Cheal; Coltness Gem, from Messrs. Purdie.

COLLALETTE.—*Awards of Merit.*—Rona, Linnet, Tuskar and Scarlet Queen, from Messrs. Dobbie; Lolah, from Messrs. Burrell. *Highly Commended.*—Tiger, from Messrs. Dobbie.

ANEMONE-FLOWERED.—*Highly Commended.*—Mons. C. H. Dupont, from Messrs. Cheal.

PEONY-FLOWERED.—*Awards of Merit.*—Aphrodite, from Mr. Turner; Faithful, Enchantress, Scarlet King and Psyche, from Messrs. Burrell. *Highly Commended.*—Nelson's Narita, from Messrs. Bath; Vesuvius and The Rose, from Messrs. Velthuys; Extase, from Messrs. Hornsveld.

SMALL-FLOWERED PEONY.—*Highly Commended.*—Trixie and Norah Dell, from Messrs. Burrell.

DECORATIVE.—*Awards of Merit.*—Mrs. Courtney Page, from Messrs. Burrell; Salmonea, from Messrs. Velthuys; Hanny van Waveren, from Messrs. van Waveren.

SMALL-FLOWERED DECORATIVE.—*Awards of Merit.*—Aglaiia and Vida, from Messrs. Burrell. *Highly Commended.*—Marianne, from Messrs. Dobbie.

CAMELLIA-FLOWERED.—*Awards of Merit.*—Fedora and Mrs. F. J. Sage, from Messrs. Burrell. *Highly Commended.*—Artis, from Messrs. Topsvoort.

SNOW.—*Award of Merit.*—Doreen, from Messrs. Cheal.

STAR.—*Highly Commended.*—Seafield, from Messrs. Dobbie; Reigate Star, from Messrs. Cheal.

DWARF CACTUS.—*Highly Commended.*—Reg, from Messrs. Treseder.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

SINGLE-FLOWERED ROSES TO GROW NATURALLY (D. D. O., Dundee).—All the varieties named are of vigorous habit and quite likely to succeed under the conditions mentioned, provided they are given a good start and the soil is kept hoed until the bushes are established. Other single-flowered varieties that might be planted are Lady Curzon, Lady Penzance, Anne of Geirsdorf, Rosa Hugonis and R. inactrantha. K. of K. is also suitable, and as it seems that singles are not to be solely used, we suggest Gruss an Teplitz, Conrad F. Meyer, La Tosca, Moonlight, Danie, Fellenberg, Sarah Bernardt, Trier and Yvonne Rabier. It will be found beneficial to cut away some of the older shoots periodically.

TREES AND SHRUBS.

TREATMENT OF LAVENDER HEDGE (F. S. N., Wylam).—The woody condition of the base of a Lavender hedge is inevitable after a time, though it does not generally happen so soon as stated (four years). We fear it is caused by undue haste in making the hedge full sized. If this had been accomplished more slowly, there would have been sufficient side shoots all the way up to keep the hedge well furnished. In the circumstances the best procedure would be to cut the hedge plants rather hard back next spring and then regulate the growths. If the planting was done thinly, it should be possible to peg down some of the branches and so assist in forming a good base to the hedge. When a Lavender hedge becomes old the inevitable should be anticipated and sufficient plants raised to replace the old ones, forming a new hedge in, of course, fresh soil.

FRUIT UNDER GLASS.

GROWING CHERRIES UNDER GLASS (H. C. F., Carnforth).—Cherries, when grown under glass, do not require any artificial heat. When the trees are at rest they need quite cool treatment and if this can be given, the trees would thrive planted in the inside border. Our correspondent may, however, grow the tree, or trees, in large pots or tubs and, when the crop has matured under glass remove the trees to an outside position, of course, paying attention to watering, etc.; this is very important, and cleanliness while the foliage is growing. Royal Duke is a good variety for growing under glass.

FRUIT GARDEN.

VARIETIES OF APPLES AND PEARS (W. U. N., Reading).—The following varieties are excellent. Apples: James Grieve, fit for use from September to November; Cox's Orange Pippin, from November till end of January; and Upton Pine or Sturmer Pippin, till end of April or even later. Pears: Marie Louise, Doyenne du Comice and Easter Buerre. The cause of our correspondent's Apples falling may be due to the fact that the fruits contained a grub which attacks the fruits when they set and gradually work their way to the core, causing them to drop off prematurely; or some outward injury may have caused the trouble. If the fruits are free from attack, then the tree is evidently wrong at the roots—the latter being in a bad rooting-medium or otherwise damaged.

APPLES UNSATISFACTORY ("Torquay").—The specimen sent for examination was affected with bitter pit. This disease is not due to any fungus or insect pest, but is in some way connected with irregularities in the flow of sap. Good cultivation goes far to prevent the complaint, at any rate, in a normal season.

MISCELLANEOUS.

CUCUMBERS DYING ("Torquay").—The Cucumber stem is completely dead and infested with myriads of decay-producing bacteria, so that it is impossible to say what has killed it. Possibly the soil contains insufficient lime or is not well drained.

LICHEN ON A LAWN (A. D., Sussex).—Ammoniacal copper carbonate will be the safest remedy. Spray or lightly but thoroughly water the part of the lawn affected with this lichen with the ammoniacal copper carbonate, to kill the lichen, and then, if necessary, dress with fresh soil and re-sow with grass.

NAMES OF FRUIT.—E. B., Bournemouth.—Apples: 1, Annie Elizabeth; 2, Werder Golden Reinette; 3, Golden Spire; 4, Bramley's Seedling; 5 and 7, Blenheim Orange; 6, Charles Ross; 8, Wellington; 9, Antonowka; 10, Keswick Godlia; 11, Too immature to identify; 12, Probably Warner's King, specimen immature.—D. H. INDIVIDUALITY IN GARDENS

THE garden-loving public may roughly be divided into two classes, namely, the picture makers and the plant collectors. The writer claims no originality in finding this out, but, banal though it be, it is worth setting down, for each has something to learn of the other. The collector might often group his collection more, with great advantage pictorially and, incidentally, with considerable saving of labour and thought, inasmuch as nearly related plants are apt to require similar treatment as regards pruning and such like. The picture maker might, if only he would study the collector's garden thoroughly, find new plants for his schemes which would give his garden a certain originality which at present it too probably lacks. The eye wearies in the end of sights, however beautiful in themselves, which have become over-familiar, and however good the colour massing, however pleasing the curves, it is hard to become enthusiastic about a garden which is for practical purposes a counterpart of many of its neighbours!

Soils and situations vary immensely, and this fact alone should go far to provide suitable variety of treatment, but does it? Almost every garden, however unsuitable the soil, must have its Rhododendron bed, yet other equally beautiful American plants are much neglected. What wonderful effects can be produced — on suitable soils, of course — by associating the mollis and mollis *sinensis* Azaleas with Kalmias, Pieris and Lilies! The evergreens

provide winter colour and a little weight of greenery for the glowing masses of Azaleas; the Kalmias provide welcome flower when the Azaleas are over, and the Pieris before the riot of colour begins. If additional summer colour is required beside the Lilies, there are various Ceanothuses to fall back upon, and groupings of Silver Birch in the background may, some of them, carry festoons of purple, rose or white Clematises.

Why is it, one wonders, that so many would-be gardeners always think of Rhododendrons in connexion with beds? The idea is a survival of the bedding tradition of a generation ago. Not only is the round or nondescript bed a very unhappy way of displaying these brilliant shrubs, it is also a very unfortunate one from a cultural standpoint, inasmuch as it is very difficult to keep plants alive in such beds—placed, as they usually are, in full sunlight—during hot, droughty

seasons. The Rhododendron is naturally a woodland plant, but where no existing growing shade is in existence such can readily be provided by suitable planting and contouring. A few Scots Pines and Silver Birches will provide a very helpful and steadily increasing screen.

Many of the named varieties of Azalea now on offer, especially the double sorts, are not worth garden room. For garden effect and real beauty a dozen Azalea mollis seedlings are worth a hundred of such. That is not, of course, to say that *no* named Azaleas are worth having. Such brilliant sorts as Anthony Koster and J. C. van Tol are, in fact, all but indispensable. What, by the way, has become of the old Honeysuckle Azalea, parent of all the Gheut hybrids, pleasing in its rich yellow colouring and thrice welcome for its delicious fragrance? To many this grand old kind comes as a new plant when they meet it. It will be found catalogued in John Waterer's list as Azalea pontica. Doubtless it may also be obtained elsewhere.

The fact that the Eucryphias are rare in gardens may be explained by the fact that hitherto they have been rather expensive (though surely one really good shrub is worth a number of mediocre ones?) or to their supposed, but quite imaginary, difficulty in cultivation. The common *E. punatifolia* is the best but *E. coriifolia* is desirable. Another family of shrubs scantily represented in the garden is the genus *Exochorda*. Their flowers, individually, are quite as beautiful as those of

THE BEAUTIFUL SNOWDROP TREE, HALEZIA CAROLINA.

BEST OF FLOWERING BRAMBLES, RUBUS DELICIOSUS.
The foliage is that of *Stephanandra Tanaka*.

THE PEARL BUSH, EXOCHORDA GRANDIFLORA.

BERBERIS THUNBERGII IN MARCH.

any of the Myrtles and are borne in elegant sprays, but through some curious perversity the Myrtle is given a wall and coaxed and protected in many gardens where *Exochorda* is not represented. White-washed Brambles, doubtfully handsome, abound, but the beautiful *Rubus deliciosus* is seldom seen.

Then how curious seems to be the general taste in shrubby *Spiraeas*! What quantities one sees of *Spiraea japonica* and its variety Anthony Waterer and the dingy white form usually catalogued as *S. callosa*. Next to these the most popular variety seems to be *S. Douglasii*, while crowds of somewhat similar but inferior species abound. Still on the descending scale of popularity we come to *S. Van Houttei*, which is really an excellent shrub, but the most beautiful of all, *Lindleyana*, *ariaefolia*, *Thunbergii* and *prunifolia* fl. pl., are those most seldom seen. Practically all herbaceous *Spiraeas* are valuable if rightly placed, but the glorious *S. palmata* should be planted wherever semi-shade and moisture can be found in conjunction. *S. Aruncus* is one of the most dignified and most generally useful of herbaceous plants. It will grow and flower in sun or shade.

Whole families of plants on someone's *ipse dixit* become branded as tender. The Daisy Trees (*Olearia*) form a case in point. It has even been stated that *Olearia stellulata* is only hardy on a wall in specially favoured districts. The fact is that in light, warm soils, given general natural shelter from the east and the hill top or, at any rate, some remoteness from the moisture-laden valley, such species as *O.O. stellulata*, the nearly related *Gunniana*, *macrodonata* and *nummularifolia* have passed safely through all recent winters in the South Midlands of England, and this without any protection whatever other than the natural shelter already mentioned. All those mentioned are, in point of fact, much hardier than such Rock Roses (*Cistus*) as *C.C. salvifolius*, *algarvensis*, *creticus* and *purpureus*. When one thinks how much more interesting these and other Daisy Trees are than the much planted *O. Haastii*, one can but wish that they may be more frequently planted in future. They are readily propagated from cuttings, and *O.O. stellulata* and *Gunniana* are quick growing, so that should a severe winter destroy them their replacement could readily be effected. The Snowdrop Tree, too, *Halesia carolina* is still scarce in gardens.

Near our seaboard the Hortensias, or Changeable Gardeners as they are also called (*Hydrangea hortensis*) flourish outdoors. The fine new hybrids are presumably as hardy as the older and less beautiful forms. Why not plant these in preference to the others? Inland gardens where the Hortensias do not stand usually contain the huge paniced *Hydrangea paniculata grandiflora*. This is an effective shrub, though hardly so graceful as the typical *H. paniculatum*, of which it is a sterile form, but it needs copious supplies of water if it is to succeed. The greenish white *Hydrangea arborescens grandiflora* is even freer to flower and withstands drought much better. True it is quite a distinct plant, but it is certainly worthy of more extended cultivation than it at present enjoys. Its chief drawback is that to see it at its best it needs a certain amount of staking or supporting, old peasticks being admirable for the purpose. The climbing *Hydrangea scandens* is also worthy of a place in gardens.

On any decent soil, but especially on those containing lime, the ornamental Plums and Cherries flourish. What a multitude of *Prunus cerasifera* *Pissardi* one sees (though its better forms, called *Moseri* fl. pl., *Blueiana* and *nigra*, are scarce enough) yet *P.P. microlepis* and *pendula*, and even the double form of the Blackthorn, *P. spinosa*, are comparatively rare in gardens.

MAPLES FOR THE GARDEN

IN the following notes no attempt will be made to describe all the species now grown in Britain, nor even all the desirable sorts. Rather will an attempt be made to select from the rather bewildering list of names a few of proved worth for various purposes. The common Maple of our hedgerows, with its very characteristic growth, beautiful bark and never-failing autumn colour, forms an admirable small tree. It is splendid for ornamental hedges where deciduous hedges are in demand, being equally as valuable as the Beech or Hornbeam for the purpose.

probably the best variegated deciduous tree which attains any size. The purple-leaved form (*A. P. purpureum*) has the foliage bright purple beneath. It is rather a dull-looking tree when seen from a distance, though pleasing on closer inspection. *A. P. brilliantissimum* is, as its name would imply, a striking tree, especially when the leaves first unfold. They are then of a bright pinkish shade.

The Sugar Maple, *A. saccharum* is rather of sentimental interest than valuable for garden or woodland in Britain. Its foliage turns yellow in autumn but the effect produced is inferior to that

handsome tree. The *Negundo* is gorgeous and the female with its huge bunches of keys the more handsome. The variety usually seen in gardens is called *variegatum*. It is handsomely variegated with white, but like all variegated trees may easily be overdone and has, indeed, been planted far too largely (and spottily) in many gardens. It is not a strong grower and has a persistent tendency to revert to the typical green form. This form is female and the keys are variegated. The golden-variegated form called *aureo-marginatum* is an altogether more robust tree than the white one, more effective and better worth planting. Variety *aureum* (*odessanum*) has leaves entirely golden. It is one of the best of yellow-foliaged trees and keeps its colour well.

Most garden lovers would consider the fancy Japanese Maples worthy of admiration in the garden. They assuredly are the most suitable representatives of the genus for the comparatively small garden. These are all varieties of *Acer japonicum* or *A. palmatum*, mostly of the latter, and represent careful selection over a long period by Japanese gardeners. The typical *Acer japonicum* is a beautiful and useful species which grows slowly but attains at last the dimensions of a small tree. It is interesting when in early spring the reddish flowers appear and again when the leaves unfold; it is a handsome tree when in full foliage; the reddish spreading keys are good to look upon and, in autumn, when the foliage takes on crimson tones, it is most beautiful of all. The smooth clean wood is attractive when the tree is bare. The most pleasing varieties of this beautiful species are the golden-leaved *aureum* and *filicifolium*, with handsome, much cut deep green foliage.

Acer palmatum (syn. *A. polymorphum*), is in the typical form less beautiful than *A. japonicum*, but many of its varieties are among the most beautiful foliage plants in existence. The palmate (five lobed) forms are, on the whole, inferior to the seven lobed (*septemlobum*) varieties. Some of the best of these latter are *elegans* with very beautiful green foliage, which turns scarlet in autumn; *elegans purpureum*, similar, but with purple foliage; *sanguineum*, leaves bright purplish red; *atropurpureum*, foliage deep purple; and *reticulatum*,

strangely mottled yellow, pale green and white on a darker background formed by the deep green leaf-veins. The typical *septemlobum* is an admirable green form which colours beautifully in autumn. Of the five-lobed forms perhaps the most useful is *A. palmatum aureum* with golden foliage; often confused with, but quite distinct from, *A. japonicum aureum*. *A. p. roseo-marginatum* has a distinct rosy edging to the leaf, but, as with many variegated leaved plants, the variegation is accompanied by considerable distortion of the leaf form and considerable loss of size. The dissectum forms are very beautiful with their much divided feathery foliage, but are hardly so strong growing as the seven or five-lobed forms. This very cut-leaved form is to be procured with green foliage, with foliage of a bronzy hue as well as with the wine red shading of *septemlobum sanguineum*. There are, in addition, variegated and rose-margined forms, all with the much-cut leaf.

Besides these (and other) forms of *A. japonicum* and *palmatum*, the Japanese have selected

A SPECIMEN ACER PALMATUM.

There are several varieties, some with mottled or variegated leaves, but the wild plant is the best.

The red Norway Maple, *Acer platanoides* Schwedlerii, forms an admirable tree, but requires room to display itself to advantage. The young foliage is bright red and the yellow flower attractive. The foliage matures a deep purplish green, but the keys are deep red and the foliage colours in autumn. There are other varieties of the Norway Maple which are worth growing, notably var. *globosum*, a small grower which forms a flattish head. All the green forms of *Acer platanoides* are valuable for red autumnal foliage colouring.

The common Sycamore (*A. Pseudoplatanus*) is a tree valuable for its extreme hardiness and easiness of culture. It is an admirable tree for near the sea coast. It may become deformed from the force of the wind, but will unflinchingly endure the salt with which the winds are laden. The Sycamore is more prone than most forest trees to exhibit variegation and the form *albo-variegatum* with bold milky-white blotches and stripes is

of the common Maple. In North America this is a very ornamental tree with brilliant autumn colouring, but it does not take kindly to our climate.

The Italian Maple, *A. Opalus*, is really beautiful when in flower in March and April. The flowers are quite a bright yellow, the tree grows well in Britain and has large and rather handsome foliage.

The Moose Wood or Snake-bark, *A. pennsylvanicum*, forms a tree of about the stature of the common Maple. It is chiefly remarkable for the white striping which distinguishes the wood when two years old and upwards. In the variety *erythrocladum*, the young wood turns bright crimson in autumn. This is one of the most attractive of Maples, being handsome of foliage and colouring well in autumn.

The Box Elder, *A. Negundo*, is now well known in gardens in its variegated forms, but the typical tree being rather gauche in its young stage is not nearly so often planted as it should be. It makes a

varieties of *A. pictum*, a much larger and quicker growing tree than the other two species. *A. pictum* itself is a sufficiently handsome tree, but the variegated forms are not recommendable. They have a considerable tendency to revert to the type and are moreover too quick in growth to associate with the palmatum and japonicum forms.

The Maples as a whole are not particular as to soil, but while by no means bog-lovers, they certainly flourish best where they have access to water. The Japanese varieties are very liable in our climate to be damaged by rough winds and by spring frosts. Shelter from rough winds and from the morning sun is therefore advisable. They succeed best in soil which will grow good

Rhododendrons. A little shade is not harmful to them, but it tends to detract from the foliage colouring. They have one great advantage in that, like many American plants, they transplant very readily, even when of some size and not recently transplanted. They may, therefore, be planted fairly closely and given more space when they grow together.

THE NEW HERBACEOUS BORDER: HOW TO MAKE IT

Really hardy border plants that flower freely, and grow well with good treatment, are increasing in favour every year. These notes and accompanying table are intended to be helpful to inexperienced cultivators who wish to form new borders either in new or old gardens.

THE list is not an exhaustive one as there is such wealth to select from, but the kinds and varieties named will answer the purpose as they are reliable, lovely in every way and, in addition to furnishing a border, will yield a harvest of blossom for cutting.

PREPARING THE GROUND.

Herbaceous plants will thrive in most soils if these are well prepared. It is quite as necessary to trench the ground for herbaceous plants as it is for fruit trees, shrubs and vegetables. Too often does one see herbaceous plants showing signs of distress about midsummer in a dry season just

when they should be in a flourishing condition. There are several causes of this, such as overcrowded roots, poor soils and lack of depth of cultivated soil. Even where every attention is paid to current details of culture, satisfactory growth will not result if the soil is very shallow in addition to being poor. Trench the poorest ground first to a depth of at least 2ft.; if leaf soil, garden refuse, which is suitably decayed, wood ashes or rotted manure be available, add such liberally to the poor soil, thoroughly mixing the materials with the soil. The roots of the plants will penetrate deeper, in consequence, and the clumps will survive a dry spell, bearing, of course, finer spikes, foliage and flowers.

Good loams will not need the addition of much manure at the time of digging; it can be applied, when necessary, as a surface mulch. Such loams should, however, be deeply trenched for many kinds of herbaceous plants root deeply, and in any case deep cultivation minimises the effects of drought. It is much better to prepare a small border thoroughly than a large one indifferently.

PLANTING AND ARRANGEMENT.

Planting may be done in open weather, any time from the end of October to the end of April as far as the majority of kinds are concerned. In the table the approximate height is stated of the kinds and varieties so that the veriest novice will be able to arrange the plants so that the tallest are in the background with dwarfer ones in the centre and front. But care must be taken to avoid a too formal arrangement. Odd plants or small groups growing a little taller than others near them, break up and enliven the appearance of the border.

Where Michaelmas Daisies are used the tall varieties should always be at the back, with the dwarfer-growing ones in the centre; these plants in themselves almost furnish a border late in the season. Ample room must be allowed for every clump to grow, without smothering others, unless, indeed, the "others" have gone out of flower.

GEORGE GARNER.

A SELECTION OF HARDY HERBACEOUS PLANTS.

Name.	Height. Feet.	Colour.	Flowering month or months.
Achillea Eupatorium	4 ..	Yellow	July, August, September.

Trollius europaeus	1 ..	Yellow	May, June.
Veronica longifolia sub-ossalis	2 ..	Blue	July, August.

THE SNAKERROOTS

AMONG the most interesting and attractive families of hardy herbaceous perennials are the Snakeroots (*Liatris*), natives of North America and quite unlike any other genus in that they commence to open their flowers from the top of the spike and continue downwards. From a cluster of grass-like foliage appear stout, straight leafy stems attaining a height of from 3ft. to 4ft., of which fully 1ft. to 2ft. is encircled with crimson-purple, star-like flowers. The flowering season is extended over a period from July to middle of September. The *Liatris* are perhaps most effective when planted between such plants as Peonies or Phloxes, their spikes towering well above. All the species thrive in ordinary garden soil in full sun or partial shade, but respond handsomely to good cultivation. They are also good bee flowers.

THE GARDEN DAHLIA

THE present-day Dahlia, apart from its obvious grouping into classes, such as Pæony, Decorative, Cactus or Show, may well be divided into three great groups, according as to whether the varieties are suitable for (1) the exhibition board, (2) general cut flower and decoration, (3) garden decoration, or (4) for cut flower and garden decoration. Some sections can be placed bodily in one or other of these categories. The Show Dahlia (this class now includes the old "Fancies") are of little decorative value anywhere. The Cactus has real decorative value when cut, but is principally an exhibition bloom. On the other hand, the quaint little Pompons are equally useful for the garden, for cutting or for exhibition. Many of the exhibition singles and some of the Star varieties, while admirable for cut flower, are too shy to be really effective in the garden. This was made especially evident on a recent visit to Messrs. J. Cheal and Sons' trial ground at Crawley. Messrs. Cheal, very wisely as we think, attach great importance to the Star class, which for decorative purposes is rapidly ousting the exhibition single as being more graceful when cut and more effective on the plant. The two first varieties of this class to be introduced, the rose pink Crawley Star and White Star, are still invaluable. Messrs. Cheal have been trying a curled petalled white seedling of more starry appearance than White Star, but it is less floriferous and though quite distinct, the flower is scarcely more beautiful than the older plant. Yellow Star is a good garden Dahlia, so is the tall upright-growing Bronze Star. A particularly fine Dahlia for cut flower is Peggy Lobjoit, and this is also quite a good garden plant, though less free flowering than Pink Star, which is hardly so good for cut flower. Purchasers must take their choice. Crimson Star is useful, but not up to the quality reached in other colours, nor as seen growing is it quite crimson. Reigate Star in shades of apricot and pink is good, but Surrey Star does not shine as a garden plant. Mauve Star, Coral Star and the newer Cuckfield Star, which is rose pink at the tips of the petals, shading off to soft yellow at the centre of the flower are all admirable; so in a different way is Primrose Star, which has several rows of petals and looks to have Cactus "blood" in it.

Of almost equal value with the Star class are the dwarf bedding "Mignon" Dahlias, but these have not hitherto been so popular, probably because the single flowers have no special beauty

of form when seen on the exhibition stand. Almost every colour wanted is now to be found in this class except pink, and it would really seem as if the pink coloration carried with it a factor for tallness, but in one way or another this difficulty will probably be overcome sooner or later. All the varieties on view at Crawley are free flowering and admirable in their several colours, but the soft yellows represented by Louise and Pembroke as delightful foils for taller plants of rich red colouring made the greatest appeal. In Mr. Joseph Cheal's private garden a circular bed filled with the camellia-flowered Crimson Flag and edged with Mignon Dahlia Pembroke was

THE CHARMING DAHLIA CUCKFIELD STAR.

wonderfully effective. Janet, bright orange, very free and distinct, and the rich yellow Daffodil were particularly taking also, but the white varieties Niveus and Albion and the bright crimsons, such as Etna, Regent and Mincio, were equally effective. Mincio, indeed, was practically as bright as that excellent variety Coltness Gem, represented in the trials only by cut-back plants.

The exhibition singles are rather set and stiff for cut flower, and for the most part less showy in the garden than the Star varieties, but there are exceptions in this last regard, and we particularly noted Butterfly, pure white with, of course, the characteristic yellow zone and the vivid crimson scarlet Leon as excellent garden plants, as well as being admirable for exhibition purposes.

Collarlet Dahlias are not very noteworthy as plants for garden decoration and, since the truth must be told, the newer sorts seem less effective

for this purpose than those first introduced. At any rate the old Carl Beckstadt, bright crimson with a yellow collar, seemed about the most effective of those under trial. The collar of this variety is rather poor and "stubby" and the petals do not lie flat; none the less, it is an excellent garden plant. Of the newer sorts Melody, a study in bronzy orange and yellow, made the best effect, always excepting the brilliant semi-double Novelty, which is a brilliant garden plant with an abundance of not too shapely flowers in bright crimson and gold.

The Pompon Dahlias are quite admirable for garden decoration, since they blossom freely and hold up their flowers well above the foliage. That they are valuable for cut flower goes almost without saying. If they have not quite the grace of, say, the Star varieties, they largely make up for the shortage by the fact that however long they remain in water they shed no pollen. It is true that if gathered before quite mature the Star varieties may be used quite safely even on the dinner-table for two days; none the less, their propensity to shed pollen is undoubtedly a drawback. One cannot say that any special Pompon variety drew attention in the trial. They were all laden with blossom, so that making a selection resolves itself largely into a choice of colours. Firefly and Freedom, both crimsons, are effective in the garden, so is the primrose-coloured Niobe and the pure white The Bride. Nerissa in mauve pink and Bacchus with orange apricot flowers we do not remember to have seen at Crawley, but they are both excellent, if old, varieties.

The Pæony-flowered class is still popular despite its affectation of modesty in the border! The Pæony-flowered varieties almost invariably carry their flowers well above the foliage, but with equal unanimity they almost all hang their heads to greater or less extent. For that reason many people prefer the tall varieties, as then, especially if they be planted on rather high ground, one looks upward to the flower. Probably a race of stiff-stemmed Pæony-flowered sorts is on the way. At any rate the new Lady Greer recently selected for trial at Wisley carries its flowers firmly on stout stems. The miniature Pæony-flowered sorts shade off by insensible degrees into the Star class. These are equally valuable in the garden and almost as good for cut flower. Especially good at Crawley were Lady Beatty, salmon pink, flushed rose, and Léonie Cobb, rosy lilac.

A large batch of the best Cactus varieties served only to shew how unsuitable these are for garden decoration. The miniature Cactus forms, however, are excellent garden plants, but varieties at present are not numerous.

The large Decorative varieties are all suitable for garden decoration, since by their suitability in this regard they stand or fall, but they shew great diversity of habit and appearance. The popular Brentwood Yellow has evidently much Cactus blood, whereas others are practically quite double "Pæonies," and others, again, like the flaming red Souv. de Gustave Douzon, are a class apart. This last type is evidently being bred for by the Dutch florists, since a number of the varieties with these huge solid flowers were displayed by them at the Dahlia Show. They certainly are showy in the garden. At Crawley these leviathans came in for their share of admiration, but the smaller camellia-flowered type seemed the more attractive. Crimson Flag has already been referred to. It might be taken as typical of a good garden Dahlia. Cheal's White represents, near enough, a white counterpart. Yellow and pink have yet to be represented in anything of the same type. May they soon be evolved

THE ASIATIC SPECIES OF MECONOPSIS

WELL do these exquisite flowers, that the botanist recognises as *Meconopsis*, merit the more English name of *Satin Poppy*, for that is exactly what they look like.

Great poppy-formed flowers, with petals of such delicate texture that they appear as though made of slightly crumpled satin. Whether seen in the early morning when the enclosing cases have but recently fallen away from the buds and the petals are but just commencing to unwrap and reveal a peep of the glorious golden stamens that cluster at the centre of the flower or at noontide, when the widely expanded blooms are at the zenith of their glorious perfection, the "aristocratic" varieties of these superb flowers are among the finest of Nature's gifts to the garden lover. I use the word "aristocratic" varieties to describe the super forms that come to us from the Himalayas, etc., for we have, among our native flora, representatives of the family in the Welsh Poppy—*Meconopsis cambrica*—which beautiful though it is when one comes upon it amid its natural surroundings, is apt to become rather troublesome when transferred to the garden, owing to its free seeding habits. Would that the alien types were addicted to the same vice, for never, never, could one weary of the marvellous beauty of such gems as *aculeata*, *nepalensis*, *Wallichii*, etc., but alas! these have to be coaxed and wooed to do their best, although the difficulties in the way are not insurmountable and splendid results may be obtained where soil and position are to their liking. Here, indeed, lies the crux of the matter. One must experiment and find the particular spot in one's own garden where they will thrive and grow, perhaps only a few feet from a previous failure. Sometimes it is full sun, at others in partial shade; my own observation favouring a spot sufficiently in the open for it to be impossible for any overhanging boughs to drip when rainy times come, but within the vital shadow where the sunlight comes through tall tree boughs.

Abundance of water is essential, yet must the soil never become wet or stagnant; a cool moist, yet

rich loam providing the best rooting medium. Many of the choicest types are biennials and must be sown annually and, when dealing with these, the best method is to raise in single pots, growing the plants on as strongly as possible all through summer and autumn. Do not allow them to become stunted; if larger pots are required, by all means provide them and see that the plants never suffer from drought for a single hour. These biennial forms are best wintered in a cold frame, always with an abundant circulation of air except when the conditions are unduly wet or extreme frost prevails.

Planting in permanent positions should be done either in late March or early April, taking care that the soil (while of the character indicated), is also deep and sufficiently moist. Many plants will flower the succeeding July, although others will not shew any sign of buds until another twelve months have elapsed. It is these that—ultimately—will make the most vigorous specimens and, in the ever increasing size of the rosettes of leaves, one can watch the promise of effective blossom accumulating.

When winter comes again, what then? Well, some slight protection is advisable and there is no better way of providing this than by fixing a pane of glass over the top, a few inches above the crown so that rain is shot off and the foliage kept dry while air can circulate freely over the plant. Species are fairly numerous and, among the

VERY DISTINCT IN FOLIAGE, *MECONOPSIS LATIFOLIA*.

choicest of these, mention should be made of *M. aculeata*, a small grower (2ft. high) from the Himalayas, with bright green leaves armed with stiff hair-like prickles. From the centre of the rosette of leaves, rises a stem, terminating in a loose panicle of purple blue flowers of large size. *M. integrifolia* is a grand thing from China which forms large rosettes of beautiful woolly green leaves, from the centre of which springs a tall flower stem bearing splendid primrose yellow flowers 4ins. in diameter, with stamens the same colour as the petals. It is interesting to note that there are two forms of this plant, that first introduced producing a single stem with the flowers on short pedicels branching from it, while that which followed produces several stems from the root, each one of which bears but a single bloom. Both are readily reproduced from seed.

M. nepalensis, native of Nepal, is a rare plant and very difficult to obtain, though strikingly distinct. The flower stems attain a height of 4ft. to 5ft., with wonderful large brick-red flowers, 2ins. to 3ins. in diameter. The flowering stem is much branched and the flowers nod on the stalk at the slightest breath of wind. *M. paniculata* makes very large rosettes of foliage covered with silky tawny hair, a vigorous stem 3ft. to 5ft. in stature rising from the centre, which bears a profusion of drooping yellow flowers. *M. racemosa* is quite dwarf compared with many varieties and does not exceed 1ft. The flowers are very like those of *aculeata*, but a delightful shade of pale blue. *M. simplicifolia* forms tufts of lance-shaped leaves, 3ins. to 5ins. in length and covered with a short, dense brownish pubescence. The flower stalks rise to 1ft. and bear, at the top, a single violet-purple flower, 2ins. to 3ins. across. *M. Wallichii* is among the choicest and finest species, capable, under the

MECONOPSIS WALLICHII IN SEMI-WOODLAND.

best conditions of reaching a height of 5ft. to 7ft. A native, once again, of the Himalayas, the foliage is exceedingly beautiful, much divided and covered with silky hairs and reaching a length of 1ft. to 18ins. These leaves are extremely brittle and, though quite capable of standing the winter, are

badly damaged by snow so that our ally, the glass pane, should certainly be requisitioned. The flower spike assumes the form of a pyramid and branches freely, the first flowers to open being those at the end of each branch, continuing until those nearest to the central stem expand. CROYDONIA.

A TRIAL OF NEW ROSES

BRITISH INTRODUCTIONS OF 1920.

(continued from page 487)

Miss M. J. Spencer (H.T., Hugh Dickson).—Strong growth. Golden yellow blooms, not unlike Golden Ophelia in the bud, and the blooms are lighter coloured on the outside petals, but it is a stronger grower than Golden Ophelia and a different type. Should make a good garden Rose, and is sweetly scented.

Mrs. Arthur Johnson (H.T., S. McGredy and Son).—To judge by the foliage and growth, it looks like a Pernetiana. Moderate growth, with large blooms rather flat, and deep orange colour.

Mrs. Chas. Lamplough (H.T., S. McGredy and Son).—An exhibition Rose of good, strong

NOTES on the AUTUMN ROSE SHOW

The Giving of Gold Medals and Awards of Merit.

THE bestowal of a gold medal on Florence L. Izzard gives me an opportunity to correct a statement in the Rose Annual for 1922 in my account of the Autumn Rose Show of 1921. I am made to say "Anyone who was on this occasion a little behind the scenes as I was could not fail to be aware that rosarians of equal experience with the judges would have made the same awards." I intended to say, as the immediate context shews, "would not have made the same awards." Exactly the same occurred this year. The selected judges made their awards, but I found rosarians of equal experience who would have given them very differently. "Who shall decide when doctors disagree?" I really cannot tell; but when this happens it does seem to give a *locus standi* to men and women who are no experts and to whom the raised centre is no fetish. Hence I venture to say that I would have given a "gold" to Mrs. Edward Molony. I liked the general form of the flowers, their pretty rose colouring, and their pleasing scent. I cannot help it, I do like rose-coloured Roses. Florence L. Izzard, the rival of Mable Morse in the last autumn show, gained the gold medal this time. It has two very good points. It has a strong Tea scent and exceedingly nice shaped buds. But I thought its yellow colouring cold and somewhat unattractive. The award, which in my eyes "took the biscuit" for non-understandableness, was the award of merit given to Mrs. C. W. Edward. Its colour was all right, but I do not think there was a bud or a partly open bloom that had not several of the outside petals greatly disfigured by weather. Mr. McGredy said, "Ah! but the foliage is mildew proof!" It may be, but its flowers are not weather-proof; anything but that, it seemed to me. My good Irish friend looked very unwell. He was just a shadow of his old self. Eight weeks of bed with double pneumonia have left their mark. All his many friends will, I feel certain, join with me in hoping that Harrogate, where he is as I write, will set him up again.

THE FLOWER OF THE SHOW.

I would not have had the least difficulty where to place the golden apple had one come from the gods on this occasion labelled "To the fairest." I would have laid it at the feet of two perfect blooms of the pure white Innocence which graced the centre of Chaplin Brothers' group at the north-west corner of the Royal Horticultural Society's Hall. The beautiful undulation of the petals coupled with their good, rich, solid look, and their charming centre with the red and rose filaments of the stamens shimmering below their yellow anthers, made up as beautiful a Rose as I ever wish to see. Pax must retire!

THE "BELLE" OF THE SHOW

Ever since I first saw Isobel in the days of her youth in her home at Portadown I have set my cap at her. I am now her humble slave. Everyone is. Isobel was here, there and everywhere; and wherever she was she added distinction and charm to the group. It is a cowardly thing to do, and I know

I am not practising what I preach, but as words fail me in attempting to convey any idea of her beautiful warm rosy pink colouring, I just say "Too well known to need any description."

CAUGHT-MY-EYE ROSES.

At every Show certain Roses catch my eye, but for some unfathomable reason they are

ROSE MRS. HENRY MORSE, BRIGHT PINK SHADED SALMON.

not by any means always the same—Los Angeles at Cardiff in 1920 took my fancy very much, yet it left me cold now. They are sometimes very new-comers, sometimes "as old as the hills." Here is the list of some of those which caught my eye on September 21: Padre, Lady Pirrie, Betty Uprichard, Mrs. Oakley Fisher, Independence Day, Columbia, Mrs. Henry Morse, Katharine Zeinet, Emma Wright, W. E. Wallace and Glowworm.

JOSEPH JACOB.

FORTHCOMING EVENTS.

October 6.—United Horticultural Benefit and Provident Society's Meeting.

October 11.—East Anglian Horticultural Society's Meeting. Sheffield Chrysanthemum Society's Meeting.

October 12.—Bristol and District Gardeners' Association's Meeting. Wargrave and District Gardeners' Society's Meeting.

and erect growth. Large pointed blooms of pale chrome colour, and plenty of them.

Mrs. Curnock Sawday (H.T., Elisha Hicks).—A strong grower and effective garden Rose with pale pink blooms; sweet scented, but unfortunately liable to mildew.

Mrs. Fred Cook (Pernetiana, W. Easlea).—Not a strong grower, although the blooms come large and pointed, and are of a light terra-cotta pink shade. Almost big enough for an exhibition box. Sweet scented.

Mrs. H. R. Darlington (H.T., S. McGredy and Son).—Again an exhibitor's Rose, creamy yellow, with big blooms carried erect on stout, strong shoots.

Mrs. John R. Allen (H.T., Hugh Dickson).—Medium growth. The blooms are rather flat and dark pink in colour, with lighter pink on outside petals. None too free a bloomer, and not yet recommended here as a garden Rose until it is established mildew-proof.

Mrs. Tom Paul (H.T., Hugh Dickson).—Only a moderate grower, with creamy yellow blooms, flushed pink. It is a fairly free bloomer, but the blooms are flat in shape.

Mrs. W. A. Lindsay (H.T., Hugh Dickson).—A good grower, with creamy pink blooms, the centres of which are tinted a deeper pink. Almost big enough for exhibition. Plenty of strong shoots and a fine bedding variety. Slightly scented.

Olive Whittaker (H.T., W. Easlea).—An excellent grower. Blooms are large, semi-single, of a dark red colour, with bright golden stamens. The buds also are very fine. A very free bloomer, and a useful garden Rose to give an effective mass of colour. Slightly fragrant.

Padre (H.T., B. R. Cant and Sons).—Without doubt the strongest-growing Hybrid Tea of this season. Upright shoots carry large trusses of blooms, reminding us in growth of Dorothy Page Roberts, but a far more profuse bloomer. Unique colour—coppery scarlet flushed with yellow, and the buds are exceptionally long in the petals. An excellent bedding Rose which should never cause disappointment.

Peggy Astbury (Pernetiana, W. Easlea).—Bushy growth, moderately strong. Semi-single blooms, and quite a unique amber yellow colour, and with serrated edges. The colour seems to wash out in wet weather, but it is a good garden Rose worth trying, especially by those in search of a novel shade of colour.

Pink Bedder (H.T., William Paul and Son).—Straggly growth. Single pink blooms, which

unfortunately turn blue on maturity. Not a handsome-shaped plant or bloom; in fact, single pinks such as this are hardly called for.

The General (H.T., J. H. Pemberton).—A strong grower, but oh! the mildew! Large trusses of globular red blooms, which blue off. The only redeeming feature of the variety is the scent of the blooms, which is exceptionally sweet.

Tim Page (Pernetiana, W. Easlea).—Erect growth, with pretty, glossy foliage similar to our old friend Louise Catherine Breslau. Heavy yellow clean blooms, rather flat and sweet scented. A free bloomer and useful garden variety.

Vanity (Hybrid Musk, J. H. Pemberton).—A cluster Rose with semi-single blooms pink in colour. Summer flowering only.

Victory (H.T., S. McGredy and Son).—Erect growth, but not very strong, and hardly a profuse bloomer. The blooms are scarlet crimson with long pointed buds. We consider this variety has already been superseded by McGredy's 1921 Rose Princess Victoria, which is far superior.

If awards had to be given for the best Roses from the above list, which is as representative of 1920 new varieties as it was possible to find, and selecting therefrom the best bedding, the best exhibition and the best climbing Rose of the season, our choice for the first would undoubtedly fall on Padre. Hawmark Crimson would be a good second and Olive Whittaker third. Of exhibition Roses undoubtedly Mrs. Chas. Lamplough is the best, and Mrs. H. R. Darlington second. One climber only could be recommended, namely, Climbing Ophelia. HERBERT L. WETTERN.

NEXT YEAR'S SWEET PEAS

Alternative Methods of Cultivation.

IF one wishes Sweet Peas in good time next summer it is advisable to lay the foundation this autumn. If an autumn sowing outdoors is in contemplation the work should be put in hand immediately these lines are in print. Opinions differ as to the amount of preliminary ground working desirable in such a case. The writer's experience is that, given really good cultivation for an immediately preceding crop, it is better not to trench the ground before sowing the seed. The objection to deep cultivation is that it is not possible to get the ground really settled again before germination takes place. For Sweet Peas deep cultivation is essential, although, unless for exhibition (and important shows at that), it really is not necessary to work ground 2ft. or even 3ft. deep as is so often recommended. It is easy (dare I say too easy?) to write of trenching ground 3ft. deep, but it is by no means so easy to carry out in practice. Trenching as ordinarily carried out moves the soil to a depth of from 1ft. to 15ins.—more often a foot than the bigger depth—and to trench land 3ft. deep will mean, even given an easy working subsoil, five or six times the labour! The light, hungry, gravelly soil at Messrs. Sutton's, Reading, trial ground will be familiar to many readers. It is impossible to cultivate such ground deeply as at very little depth, nowhere more than a foot, one strikes clean, practically sandless gravel; yet by adding a few inches of loam to the surface — one way of getting depth—the Reading firm have succeeded in growing Sweet Peas which have proved a source of delight to countless visitors to London and Provincial shows! Still, deep cultivation must be practised if satisfactory results are to be obtained and if a recently trenched site is not available, the trenching

should be put in hand at once and the seeds be sown in pots and planted out in the then consolidated trench next spring.

Sowing in pots is generally considered to give better results than sowing direct in the trench, but *provided the plants stand the winter*, I am by no means certain of this. Alas! there's the rub! In the Midlands the plants often do not survive the trials of our changeable winters and even in the South there is an element of chance in the matter. If seeds are to be sown in pots, a nice turfy loam makes a satisfactory compost with, if alone it would tend to "set" too stiffly, a little manure from a spent hot-bed and, perhaps, a little coarse silver sand. It is wiser not to use leaf mould. For exhibition it is well to sow the seeds singly (having proved their germination by the simple expedient of just planting them in silver sand), in 3in. "Long-Tom" pots. This method takes up a deal of space, however, in the frames allotted for the purpose, more space, indeed, than is always available. This being so, many growers sow three or four seeds in a 5-in. pot (if "Long-Tom" so much the better!). The pots should be placed in a cold frame looking either south or south-west and some protection should be available should hard weather ensue, since the plant does not exist which likes to have its roots frozen inside a flower pot, to say nothing of the broken pots which are likely to be found when the thaw sets in! Border Carnations will probably withstand cold as well as any plants grown in our gardens, but even the Carnation specialists take steps to protect their young plants from being frozen solid in the frames! Beyond the necessary watering the young plants in pots will need little attention until early spring, though a sharp look-out must, of course, be kept for slugs and snails.

"Do plants raised from seeds sown in pots in autumn do better than those started early in the New Year?" is a question often asked. In the rather dry southern counties they certainly do, as the thoroughly well rooted plants establish themselves more quickly. Even further north they should have an advantage, but an exception must be made in the case of the suburbs of smoky towns. Winter fog and bad light tends to make anæmic plants. Artificial heat to the young plants also makes for debility. In the open country an English winter provides enough light for vegetation which, above ground, is practically at a standstill. Give artificial heat and growth commences and, there being an insufficient of sunlight to ripen the growth as formed, the plants become attenuated and their constitution is greatly impaired.

So much for the young plants which are to inhabit our trenches in the spring, but what of the trenches themselves. If an abundance of good, partially rotted horse dung (on heavy land), or cow dung on lighter soils, is available, it will be well to incorporate it well with the soil of each spit except the top one, but if there is a shortage, it will be better to reserve it all for the spit immediately below the top one. Other ingredients should depend somewhat upon the character of the soil and its active constituents, but it will do no harm to include a fair amount of wood ashes from the garden bonfire—if these contain a little charcoal, so much the better—and a couple of ounces to the square yard of finely ground bones. This is a safer fertiliser to use than bone meal, which too often contains an excess of free acid. Superphosphate of lime, which is admirable for Sweet Peas, may well be left until the plants are established and applied dissolved in water. The same remark will apply to such soluble nitrogenous manures as sulphate of ammonia or nitrate of soda.

The cultivation of Sweet Peas under glass is a test of a gardener's ability and knowledge of the basic principles which underlie horticulture. Most amateur gardeners make the mistake of sowing the seeds too soon and bringing the plants along too quickly. Exactly similar treatment to that afforded the plants intended for outdoors should prevail until lengthening day and strengthening light make healthy growth possible. Some of the big growers for market grow Sweet Peas under glass with haulm as robust as most amateurs can achieve outdoors! SUSSEX.

EDITOR'S TABLE

FROM Messrs. John Forbes (Hawick), Limited, there came to hand recently some magnificent spikes of large-flowered Pentstemons. These flowers are very difficult to describe in such a way as shall be helpful in making a selection. One needs really to see spikes or preferably, of course, the growing plants. Take the varieties which can only be described as rose-pink, white throat. The combined effect gives a fairly light and very pleasing light pink, as seen in the mass, but the description would suffice for Mrs. Joseph Chamberlain, Miss Botley (though the throat in that case is margined cinnamon and the colour rather deeper), Mrs. Callander, Mrs. A. P. Lyle (a very fine and towering spike), or the pretty Marchioness of Tullibardine. Fine spikes of all these varieties were included, together with representative crimson and purple-flowered varieties including Earl Haig, Alex. McRae and James McLeod, crimson, and A. Douglas Haddon, Dr. Barrie, Mrs. Murray and Miss Stewart Peter of the purplish class. A posy of blossoms of that brilliant Mignon Dahlia, Coltness Gem, was also included.

CORRESPONDENCE

THE TWELVE BEST SHRUBS.

IT has often occurred to me that an interesting subject for discussion in your correspondence columns would be on the best twelve flowering shrubs for gardens. To simplify the issue it might be well to stipulate that they should all be suitable for massing (not necessarily to an equal extent, however!), and that the soil for which they would be intended should be a rather light loam, such as suits the generality of shrubs.

My own selection would include a good Lilac (say *Souv. de L. Spatti*), a good Broom (*Cytisus scoparius Andreanus*), three Barberries (*B.B. Darwini*, *stenophylla* and *Aquifolium*), the Pearl Bush (*Exochorda grandiflora*), *Spiraea Lindleyana*, *Ceanothus Gloire de Versailles*, *Rhododendron Pink Pearl*, *Pieris floribunda*, *Escallonia macrantha* and *Rose Conrad F. Meyer*. It is only when one comes to make such a list that one realises what a variety of shrubs there now is and how really difficult it is to make a selection. Yet there must be many gardens which, if the shrubs are to be displayed effectively (and in groups), can only accommodate a dozen varieties or less. I hope some other of your correspondents will give their views as to the best dozen.—G. HARVEY.

[Our correspondent's suggestion is an interesting one and we shall be glad to hear readers' views on the matter. Our correspondent stresses the importance of grouping, but in a small garden we should, ourselves, group specimens of the different species and varieties of one genus or sub-genus together. This method enables a greater variety to be included without making for unnecessary

'spottiness.' It will be noted that the list given contains shrubs known practically to everyone. All of them are certainly excellent. It is a pity space could not be found for the beautiful *Eucryphia pinnatifolia*. Most people would probably prefer it to the *Pieris*. Not everyone will choose *Pink Pearl* as the best *Rhododendron* and few, we think, *Conrad F. Meyer* as the best *Rose* for the shrubbery. There are a number of fine *Rose* species which many would think more suitable.—ED.]

THE NEW ZEALAND FLAX.

HAVING for many years been a subscriber to THE GARDEN, I thought I would send you a photograph of a bed of New Zealand Flax (*Phormium tenax*) plants that have not flowered before during my residence here of thirty-seven years. The stems of the flowers are 11ft. to 12ft. high and the Flax leaves about 7ft. The picture does not really shew the height.

I should have had the figure of a man by it, but did not think of it.—H. G. GILES, *Com. R. N.*, *Alderstoake, Hants.*

FOR THE WOODLAND.

FOR open places in woodland or the margins of shrubberies I have found *Buphthalmum (Telekia) speciosum* a bold and striking plant, with great heart-shaped leaves in a lively green well above which are raised the tall and branching flower stems. The blossoms, which appear in summer and carry on well into autumn, are of the composite type, 2ins. to 3ins. in diameter, with long, narrow rays of a deep golden yellow which blends peculiarly well with the prevailing tints of approaching autumn. This is a free-growing, hardy perennial which will do well in almost any soil and one that looks particularly effective in groups of considerable size. Though doubtless a sun lover, *B. speciosum* does not object to half shade. A. T. J.

Many people who have no fondness for its flowers, which

are rather coarse individually and have a "greenish" smell, yet tolerate this plant gladly because of its attractiveness to coloured butterflies. Red Admirals, Peacocks and both species of Tortoiseshell are much attracted by it.

THE NEW ZEALAND FLAX IN FLOWER.

It certainly is an attractive and stately plant for wild garden or woodland.—ED.]

IDEAS FOR AUTUMNAL TABLE DECORATIONS.

THE season of autumn is drawing near and as we walk in our gardens or along the country lanes we note signs of its approach in the yellowing leaf and ripening berries and nuts. This year is especially noticeable for its show of wild fruits, and the Rowans, the delight of the artist and designer are scarlet with their clusters of berries, while *Rose hips* make no less decorative a subject. Fruits and autumn leaves make a welcome change for the vases in the house, after the profusion of summer flowers, and charming table decorations of endless variety may be carried out with them.

In the English bungalows in India, the native servants often make most artistic table decorations of petals, flower heads and leaves, laid upon the cloth in conventional or natural patterns round the lamps and flower vases and, though these schemes may be a trifle bizarre, the idea can be carried out in more artistic form with great effect. A central vase of bright *Rose hips* and leaves, such as those of the *Japanese Roses*, *Hybrid Sweet Briars* or *Moyesii*, with a pattern laid out upon the cloth in separated leaves around the vase and small bunches of hips at the corners or interspersed make a delightful decoration for a small table. A few

BUPHTHALMUM SPECIOSUM IN WOODLAND.

sprays of Blackberry bramble with fruit, surrounded by bunches of Cob or Hazel nuts picked with some foliage, and four corner bunches laid upon the cloth, is very effective. Crab Apples lend a vivid dash of colour among the Nuts in this scheme. For a more elaborate decoration, autumn leaves with trailers of "Traveller's Joy" (Wild Clematis), circling the table lamps and vases can be made to look charming. There is material in plenty in our gardens and hedges to suit individual taste, and our luncheons and dinners may be quickly and tastefully decorated so that the table furnishes a feast for the eye as well as for the appetite.—M. E. B.

A HINT TO ROSE GROWERS.

I HAVE been very interested to read Mr. Wettern's opinion of the New Roses of 1920 and am anxiously awaiting the concluding portion. I do wish our nurserymen would not attach to new Roses, even after they have grown them for a season or two, the raisers' description, or an abbreviation of it. Such a description is quite valueless for shewing the real worth of the variety. I was really moved to write this letter by receiving a rose list which not only appears to contain *original* descriptions, but has very candid opinions of Roses of recent introduction, including most of the 1921 novelties. Will other rose-growers kindly copy! The list referred to is that of Messrs. A. J. and C. Allen of Norwich. I have not tried their trees so far, but shall certainly obtain what few I need this season from them as I have heard excellent reports of their stuff from friends. I have no interest whatever in the firm.—T. H. W.

WALLFLOWERS IN WINTER.

AS soon as the summer bedding plants have been removed, I find it a good plan to substitute Wallflowers. The Wallflowers are valuable during the winter months on account of their nice green foliage. In the spring the plants will produce a wealth of blossom. Apart from their beautiful colours the flowers will be greatly welcomed on account of their delightful fragrance, coming at a season when fragrant flowers are somewhat scarce. The Wallflowers will have fulfilled their important part in the embellishment of our gardens in time to make way for the early summer flowers.—G. H.

A NEGLECTED PERENNIAL, TROPÆOLUM.

THE glory of *Tropæolum speciosum* where it thrives and garlands with its scarlet flowers the fronts of houses or clammers over hedges and shrubs, has perhaps militated against the greater employment of other perennials of the same genus, but there have been other causes at work to hinder the gardener from utilising the charming *T. tuberosum*, whose pretty green foliage and scarlet and orange flowers are so attractive in their own way. The main drawbacks to its use are its shyness of flowering in some gardens and its want of complete hardiness in certain soils and districts. Its shyness of flowering has often been the subject of complaint and some ninety years or so ago, as we gather from the horticultural literature of the time, it was troublesome, and numerous devices were tried to overcome the difficulty. Now, however, that we seem to have grasped the fact that there are free-flowering as well as shy stocks, and that by a process of selection and careful elimination of poor stocks we can obtain much better results, it should become more popular. The other defect of want of hardiness in some places is not easily overcome. It is certainly not safe to leave out the tubers in winter, except in a

very well drained soil and in fairly mild districts. The prudent course is to lift the curious tubers after the foliage has been cut down by frost and to store them in dry sand out of the reach of frost until spring, when they can be treated like Potatoes, and either planted out in April, at a depth of 6 ins. or so, or started in boxes and put out in May after danger from frost is over. Where happy, this charming climber will give masses of its scarlet and orange flowers in July and August and until frost comes to deprive it of its beauty.—S. ARNOTT.

WILD FLOWERS AT COUNTRY SHOWS

LOCAL flower shows are of immense interest and benefit to the districts concerned, and where gardens are not exactly the strongest point they may be augmented by industrial exhibits and even by dogs, as in the case of one visited recently. Here very good prizes also were offered for wild flowers, which were certainly excellent—I have never seen a more varied assortment. They gave me food for much thought and the reason for this note. "The best bouquet of Wild Flowers," is usually the wording of the schedule—and the poor unfortunates are tightly tied up

FOR INDOOR DECORATION.

ONLY those who have seen leaves and berries adequately used as a table decoration can realise the beautiful effects possible. Many years ago it was my duty to assist in the work of decorating a nobleman's dinner table in one of the northern counties. In the shooting season it was usual to have a different scheme of table decoration each night for about six weeks, and, although the garden was a large one and well furnished, the tax on it was very considerable. One year the head gardener sent out several men to collect berries, leaves, moss and bark in the woods. Flowers were not used at all, the table—more than 20ft. long—being decorated entirely with the foliage and berries. Result—general approval and a request to repeat the decoration several times!—GEO. GARNER.

A FINE YELLOW TRAILER.

WHY is it, I often wonder, that that brilliant yellow trailer, *Tropæolum polyphyllum*, is so seldom seen in gardens? One can easily understand why *T. speciosum* is not largely grown in Southern gardens—because it is difficult. The lack of appreciation for *T. tuberosum* is also explicable. There are so many folk nowadays

THE GOLDEN TROPÆOLUM POLYPHYLLUM AMONG ROCKS.

regardless of number or arrangement and crammed into a jug or other receptacle much too small for them. In this case, to the credit be it said of the exhibitor, the specimens were all very carefully and correctly named, although it was difficult owing to the overcrowding to find the labels on all the ninety or more specimens in the first prize collection.

With all due deference to committees and generous prize-givers, I would respectfully make the following suggestion:—All wild flowers to be shewn arranged in the natural order, one order only in a vase—the number of species in the vase limited according to table space. For the largest orders two or more vases might be necessary. The name of the order on a large label with the specific names below. Points to be given for the largest number of orders represented and further points for the species.

Educationally this should prove beneficial both to exhibitors and visitors alike, and give our beautiful wild flowers a better chance of being appreciated at their true value.—W. DUGGAN.

who will not grow even *Gladioli* because the corms must be lifted and stored; moreover, the quaint plant with the turban-like tuber is more lavish of growth than flowers in some gardens. I can only attribute the lack of appreciation of *T. polyphyllum*, however, to its easiness. Quite hardy outdoors here in Warwickshire, it increases year by year without dividing or attention. If it sometimes flings its beautiful glaucous trails and gallant yellow blossoms over other plants, these seem none the worse when at length the trails wither and are removed.—H. H.

NARCISSUS BERNARDINO: A CORRECTION.

BERNARDINO intended to say (September 23, page 480) "I am not a politician and my other habits are good." The quotation from Artemus Ward's Fourth of July Oration was suggested by the parallel changeableness of certain politicians and the colour of its cup under the stress of external conditions.—JOSEPH JACOB.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

General Work.—Take the opportunity on dry days to eradicate weeds, particularly from where crops are still growing and will be occupying the ground for several months. Where the main batch of Leeks were not holed in, a little moulding up may be necessary so that blanching may be commenced. Turnips fully grown should be lifted and stored in a cool outside pit, otherwise they will become pithy and useless. During the brightest part of the day push on with the lifting of late Potatoes. Should there still be Tomatoes outside, the trusses should now all be cut and those not worth ripening off will be useful for chutney.

The Flower Garden.

Roses.—Planting-time will soon be with us, and where a considerable quantity has to be dealt with, necessitating the making of new beds, the preparation of such should be seen to in good time, so that no delay need be experienced when planting-time actually arrives. Should the order not yet have been placed, no time should be lost before doing so.

The Hardy Fruit Garden.

Fruits to Plant.—To attempt much advice on this subject in a brief note is quite useless, but for the benefit of intending planters who have neither the time nor inclination to go into the matter very much a few reliable varieties are given below. It must be distinctly understood that no attempt has been made to make out an up-to-date, comprehensive list. The order of ripening may be taken as names are given. *Dessert Apples.*—Beauty of Bath, James Grieve, American Mother, Ribston Pippin, Cox's Orange Pippin and Wyken Pippin. *Culinary Apples.*—Lord Grosvenor, Stirling Castle, Bramley's Seedling, Lane's Prince Albert and Newton Wonder. *Dessert Pears.*—Williams's Bon Chretien, Beurre d'Amanlis, Marie Louise, Doyenne du Comice, Glou Morceau and Josephine de Malines. *Culinary Pear.*—Catillac. *Dessert Plums.*—Rivers' Early Prolific, Oullin's Golden Gage, Green Gage, Jefferson and Coe's Golden Drop. *Culinary Plums.*—Czar, Victoria and Monarch. *Damsons.*—Frogmore Prolific and the Merryweather. Prospective planters with but little experience of soils and suitable varieties would do well to get in touch with a good local grower and get his advice, or give particulars of soil, etc., to a reliable nurseryman.

Fruit Under Glass.

Tomatoes.—Should the winter fruiterers have been growing outside they should at once be housed, for no reliance can now be placed upon the weather. To obtain good results a light, airy structure is necessary with only the welfare of the Tomatoes considered. By keeping the hot-water pipes nicely warmed plenty of air can be kept on, and this is most important, particularly for the first few weeks after taking the plants indoors. About four trusses of fruits are enough for each plant to carry, or less if the plants are not in good health. As the days become shorter and less sunny avoid overwatering, and care should be taken with the application of stimulants.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cucumbers.—Plants coming into bearing must be accorded considerable treatment at this time if the crop is to be a success. Maintain a night temperature of 95° so that free growth may be encouraged, at the same time being careful to see that all unnecessary growths are kept well thinned out and only a moderate quantity of fruits left to develop. Spray only on fine days, as a low temperature and dull, sunless weather encourages the spread of mildew. The plants will benefit by occasional top-dressings of loam and leaf-mould.

Winter Spinach.—During dry weather this important crop should be further encouraged by frequent stirring of the soil between the rows. Make sure that the plants are not too dense in the rows, otherwise the foliage weakens and suffers more readily from severe frost than that

which has been allowed more space to develop a sturdy growth.

Tomatoes.—Continue to assist all late-fruited plants by giving frequent applications of weak liquid manure. A little warmth must also be kept in the pipes now so that the ripening of the fruit may be quickened. In establishments where winter-fruited Tomatoes are grown the flower trusses should be lightly tapped every day to assist in fertilisation.

Winter Salads.—Attend to batches of Lettuce in frames, keeping the soil well stirred and giving a light dusting of soot around the plants to keep slugs in check. Mustard and Cress will now prove more satisfactory if grown in boxes in a warm greenhouse or forcing pit, sowing every ten days or so.

Seakale for Forcing.—In gardens where this delectable vegetable is grown in quantity for forcing purposes every opportunity should be given the crowns to ripen properly, so where the foliage is turning yellow it should be removed, thus allowing the crowns to be more fully exposed to the influence of sun and air.

The Hardy Fruit Garden.

Fruit Picking.—Gather Apples and Pears whenever ready, exercising extreme care in handling. See that no damaged fruit is stored. All windfalls should be laid aside and used first. After the trees are cleared of their crop all broken or lacerated branches should be cut clean off and the wounds painted with Stockholm tar.

Fruit Under Glass.

Vineries.—In late vineries where the Grapes are now ripening freely the utmost care must be taken when ventilating the structures, as the shortening days and the cold, damp nights all tend towards encouraging mildew or rotting of the berries. Assist the ripening process by the judicious use of fire-heat, maintaining a warm, dry atmosphere. If a mulch of dry litter is applied to the border it will check evaporation and thus save the necessity of frequent watering.

The Flower Garden.

Pæonies.—These plants as a rule resent being disturbed about their roots, but established beds will give satisfaction for several years if accorded a liberal top-dressing of farmyard manure at the start of the growing season. Where the planting of new beds or groups of these plants is contemplated no time should now be lost in having the ground prepared for their reception. Dig the beds deeply, at the same time incorporating a generous quantity of well rotted manure and leaf-mould. Do not plant too closely, allowing reasonable space for the plants to develop and show their handsome blossoms to the best advantage.

Wintering Bedding Plants.—The softer growing types of bedding plants which are generally stored in genial quarters for the winter, such as Heliotrope, standard Fuchsias and Lantanas, should now be dug up and potted, placing them in a warm, moist pit for a week or two until they have recovered from the check. Roots of Lobelia cardinalis should also be lifted now and packed closely together in ordinary cutting boxes, working sand or fine soil round the roots. Stand the boxes in a cool frost-proof frame for the winter. Tuberous Begonias should also be lifted now and laid in a frame until the foliage dies down, when they can be stored in a dry loft where they will be free from frost.

JAMES MCGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coddham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Crocuses as represented by the large named varieties of *C. vernus* are well worth growing in pots or pans for the cool greenhouse; in fact they are ideal for the small unheated house. They are also excellent for growing in bowls of fibre. Their cultivation is of the simplest, as they grow well in any ordinary good garden soil and require cool treatment; in fact, any attempt at forcing will end in failure. If brought on in a cool greenhouse they will flower just before those growing outdoors. After potting they should be stood outdoors and covered with ashes. Any of the named varieties are suitable for this work, and they can be had from pure white through varying shades of lilac, blue and purple, as well as striped. The many beautiful spring-flowering

species are also suitable for growing in pots or pans for the small unheated greenhouse, or even with the shelter of a cold frame. Mice are very fond of Crocus corms, and a sharp look-out must be kept for them at all times, whether the corms are in store or potted up.

Irises and Other Bulbous Plants.—There are many beautiful species and varieties of Iris that may be successfully grown in pots for the cool greenhouse. Although they are all more or less hardy, they are well worth the shelter of a cool house or frame, as many of them flower so early that they are apt to get damaged by inclement weather. The species and varieties suitable for this work are the bulbous-rooted section as represented by *I. I. alata* and its varieties, *Bakeriana*, *Danfordia*, *orchioides*, *reticulata* and its varieties, *Vartani*, *persica*, *Histrio*, and *tingitana*, the latter a tall-growing species which is worth growing in quantity for cutting. Grown in this country, it is very shy flowering, but imported bulbs usually flower freely. The English and Spanish Irises may also be grown in pots, and are worth growing in quantity in boxes for a supply of cut flowers. The *Onocycclus* and *Regelio* species are notoriously difficult, but *I. I. iberica* and *Susiana* can be successfully grown in pots, and always attract by reason of their extraordinary colouring. The *Regelio-Cycclus* hybrids are more amenable to cultivation, and there are many beautiful varieties among them, some of the most distinct being *Artemis*, *Charon*, *Hecate*, *Hera*, *Jocaste*, *Mars*, *Osiris* and *Psyche*. They require a good medium loam, with the addition of old mortar rubble, to ensure free drainage; three or four good rhizomes may be placed in a 6in. pot. They should be stood in a cold frame fully exposed to all possible sunshine. Water very carefully until they have made plenty of roots and have commenced to grow. They require perfectly cool treatment, and should be given plenty of air on all favourable occasions. The rhizomes should be potted up within the next month or so. There are quite a number of bulbous and tuberous rooted plants that should be more generally grown for the cool greenhouse. Some of the smaller-growing ones are well suited for the small unheated greenhouse, *Scillas*, *Muscarias* and *Chionodoxas* being good examples of what I mean. There are quite a number of others, such as *Allium neapolitanum*, which produces a profusion of pure white flowers. *Anemone fulgens* can be very fine if well grown in 6in. pots. Some old mortar rubble should be added to the potting compost, as this plant is a lime-lover. The double *Anemones*, such as *King of the Blues* and *King of the Scarlet*, are also well worth growing in the same way, while the blue *A. apennina* and *A. blanda* should be grown in pans. *Ismene calathina* also does quite well in an ordinary greenhouse, while *Ixiolirion Pallasi* is very pretty if some six or eight bulbs are grown in a 48-sized pot. *Moutbretia rosea* is also very graceful and free flowering, and is best grown in 6in. pots. *Ornithogalum arabicum* is a very beautiful plant, but is very uncertain in flowering. The examples given will serve to show that there are quite a number of plants that can be used for this purpose. It is true many of them are hardy, but it is a great pleasure to many people to enjoy their beauty indoors in the cool greenhouse. Their cultivation is of the simplest, as most of them grow freely in any ordinary potting compost. They only require the shelter of a cold frame until such time as they show signs of flower, when they may be removed to the greenhouse. Hyacinths and all other bulbous plants used for forcing should now be potted with as little delay as possible.

Royal Botanic Gardens, Kew.

J. COITTS.

TRIALS AT WISLEY

PERENNIAL PHLOX.

The following awards have been made to Perennial Phloxes by the Council of the Royal Horticultural Society after trial at Wisley.

WHITE.—*Award of Merit.*—Mia Ruys and Frau Ant. Buchner, sent by Mr. Jones and Messrs. Ruys; La Neige, sent by the R.H.S.; Abel Tasman and Netty Stuart (*suffruticosa*) = Snowdon, sent by Mr. Jones; Europe, sent by Mr. Jones, Messrs. Forbes and Messrs. Ruys.

PINK.—*Award of Merit.*—Selma, sent by Mr. Jones, Messrs. Ruys and Messrs. Forbes; Mrs. W. Hargreaves, sent by Mr. Jones; Bridesmaid and

Liberty, sent by Mr. Prichard. *Highly Commended*.—Peach Blossom, sent by Mr. Prichard; Mrs. A. H. Dykes, sent by Mr. Jones; Mnie. Paul Dutrie, Mrs. Milly van Hoboken, Panthéon and Météore, sent by Mr. Jones and Messrs. Ruys.

SALMON.—*Award of Merit*.—Elizabeth Campbell and Mrs. Scholten, sent by Mr. Jones and Messrs. Ruys; Mrs. F. P. Steward, sent by Mr. Jones. *Highly Commended*.—Evelyn and America, sent by Mr. Jones and Messrs. Ruys; C. Edwards and W. Robertson, sent by Mr. Jones; S. Pope, sent by Messrs. Dickson and Robinson; Marion Riddle, sent by Messrs. Forbes; Cocinea, sent by Mr. West.

ROSE.—*Award of Merit*.—Jules Sandeau, sent by Mr. Jones and Messrs. Ruys; Württembergia, sent by Messrs Ruys (the above two varieties are considered identical); Thor, sent by Mr. Jones and Messrs. Ruys; Mrs. Callander, sent by Messrs. Forbes; Elsie Walker and H. J. Jones, sent by Mr. Jones. *Highly Commended*.—Splendour and Glory, sent by Mr. West; Rijnstroom, sent by Messrs. Ruys, Messrs. Forbes and Mr. Jones; Knucken, Florrie Freeman, Tom Abbott, Muriel Rogers and Marshal French, sent by Mr. Jones; Lady Wilson Todd, sent by Messrs. Forbes; Mrs. Noordewier, sent by Messrs. Ruys.

ORANGE-SCARLET.—*Award of Merit*.—General van Heutz and Mrs. Bevil Fortescue, sent by Mr. Jones; Minnie West and Brilliant, sent by Mr. West; Deutschland (= Homeland) and G. A. Strohleim, sent by Messrs. Ruys, Messrs. Forbes and Mr. Jones. *Highly Commended*.—Baron van Dedem, sent by Messrs. Ruys, Messrs. Forbes and Mr. Jones; Ruby King, sent by Mr. Prichard.

MAUVE.—*Award of Merit*.—Mrs. L. Stewart Watson, sent by Messrs. Forbes; Lofna and Marie S. Jacob, sent by Messrs. Ruys and Mr. Jones; Mrs. H. Rossitur, sent by Mr. Jones. *Highly Commended*.—Asia, sent by Messrs. Ruys and Mr. Jones.

VIOLET.—*Highly Commended*.—Marvel, sent by Messrs. Forbes.

PURPLE.—*Highly Commended*.—William Ramsay, sent by Messrs. Ruys and Mr. Jones.

FLUSHED.—*Award of Merit*.—Mrs. H. J. Jones and Mrs. A. Jeans, sent by Mr. Jones; Riverton Jewel, sent by Messrs. Ruys and Mr. Jones.

BEET.

THE following awards have been made to Beet by the Council of the Royal Horticultural Society after trial at Wisley. Judged August 2, 1922.

Award of Merit.—Egyptian re-selected, sent by Messrs. Carter.

Highly Commended.—Crimson Globe, sent by Messrs. Hurst; Express Crimson Globe, sent by Messrs. Dickson and Robinson; Reliance Globe, sent by Messrs. Webb; Eclipse Turnip-rooted, sent by Messrs. Barr; Perfect Model Globe, sent by Messrs. Kelway.

Commended.—Globe selected No. 2, sent by Messrs. Dobbie; Crimson Globe (sent as Model Globe), sent by Messrs. R. Veitch; The Cooper-Laber Turnip-rooted, sent by Messrs. Cooper, Taber.

Judged August 16, 1922:

Award of Merit.—Feltham Intermediate, sent by Messrs. Watkins and Simpson.

Highly Commended.—Intermediate, sent by Messrs. King; New Intermediate, sent by Messrs. R. Veitch; Queen Mary, sent by Messrs. Harrison.

SWEET PEAS.

THE following awards have been made to Sweet Peas by the Council of the Royal Horticultural Society after trial at Wisley:

Awards of Merit.—Hebe and Fair Lady, sent by Mr. J. Stevenson; Hawlmark Salmon-

pink, sent by Messrs. A. Dickson and Messrs. Cullen; Cottage Rose, sent by Messrs. Birtles; Royal Cherry, sent by Messrs. H. Dickson; Doris, sent by Messrs. Dobbie, Messrs. King and Messrs. Webb; Picture, sent by Messrs. Dobbie and Messrs. Webb

Highly Commended.—Mavis and Mignonne, sent by Messrs. King; Joan of Arc, sent by Mr. J. Stevenson; Annie Bownass, sent by Messrs. Cullen and Messrs. A. Dickson; Hawlmark Pink No. 1, sent by Messrs. Unwin and Messrs. A. Dickson; Rosamund, sent by Messrs. H. Dickson; Glory and Mrs. Jessop, sent by Messrs. Bolton; Hawlmark Cerise, sent by Messrs. A. Dickson; Eva, sent by Messrs. S. F. Curtis.

HALF AN HOUR AMONG THE SHRUBS

THESE is no day in the year when one cannot find some special interest in the garden. During the growing season every twenty-four hours brings big changes. Spring, of course, takes premier place for development, but the days as they go on through the year bring other changes in general feature, and it is wonderful what special beauty can be found even on the dearest and dullest day of winter. Some effect of light or shade will bring out the colour of some special plant which on another day is passed over.

To-day, brilliant sunshine and light following yesterday's heavy rain and wind, the first touches of autumn colour and fruit were the dominant features, and I specially noted a wild Cherry poking its head through the Chestnut and Oak, a brilliant patch of yellow and crimson. Snowy Mespilus on one side is already beautiful, and Acer Ginnala, one of the Chinese scrub Maples, is glorious in a sunny corner on rather poor ground. One or two of the Japanese Maples are also doing their bit. But most brilliant of all, as far as to-day's foliage is concerned, was a good-sized bush of *Vaccinium pennsylvanicum*, and one of its great charms is the length of time it holds its foliage.

Some of the Berberises caught my eye to-day, and surely as some of the varieties of this wonderful family become more generally known they will be planted in quantity. Those I saw specially were *B. lucida* with its rather large fruits, brilliant red, and the weight of the fruit on each bough sufficient to separate them in graceful semi-pendulous fashion. *B. asiatica*, with its fruit partly black with ripeness and the remainder coloured with a glaucous bloom, shone like silver with the sun touching the fruit still laden with the moisture of the night. *B. brevipaniculata*, *B. subciliolata* and *B. coccinea* were all laden with fruit and a joy to behold. A plant of *B. verruculosa* planted on a dry poor bank was turning colour and was a rich crimson, with the silvery shine of the underside of the leaf shewing up as the wind from time to time rustled through the foliage.

Some American Thorns are laden with fruit, and many of these bear well in this country and give every promise of being a valuable addition to our gardens, where fruit and autumn colour are always welcome. *Crataegus durobrivensis*, *C. mollis* and *C. cordata* are worthy of a place in any collection. The last time I was over in the States I was much struck with the wonderful collection of these plants, collected to very large extent by Professor Sargent himself and running into many hundreds of species. Among them I specially remember the section of what he called dwarf forms, which may eventually prove to be good plants over here.

Aronia floribunda was very beautiful with its black fruits and foliage already in full autumn tint.

Cotoneasters are bearing their various tints in great profusion, and I was specially charmed with the flowers of *Buddleia magnifica* and *Ceanothus Gloire de Versailles*. F. GOMER WATERER.

DAFFODIL SILVER PLANE

A Great Dominion Flower.

DURING the first week of September I have been enjoying the sight of this very excellent Daffodil in my own garden in superb condition. I doubt if anyone in England has ever seen the variety, except he happened to be at Christchurch Show early last September, or, better still, to have paid a visit to Sir Heaton Rhodes' famous garden—Otahuna—at Tai Tapu about the same time. In the happy days when I was able to get about among Daffodil people we often used to discuss the quality of Dominion-raised flowers. At the moment I can only recall two varieties which have ever appeared in decent form at English shows, viz., Pink 'Un, a famous Australian flower, and The Hon. R. J. Seddon from New Zealand. Both, at different times, were exhibited by Mr. A. M. Wilson and attracted much attention. Pink 'Un is a very good flower—quite, in my opinion, first rate, but other judges thought the pinky colouring of the edge of the large cup was not decided enough and gave it rather a washy appearance. In Silver Plane New Zealanders have a variety of which they may well be proud, and I heartily congratulate Mr. Lowe and Sir Heaton Rhodes on its production. Need I say more than that it would grace any twelve ever shown in the Bourne Cup Competition, and I have seen all of them except those of 1922? My good friend Bourne, certainly one of the best judges who ever judged a Daffodil, loved Diana; he told me so more than once, and at his death, when his collection came into the market, I was not surprised to see that he had more of this than of any other variety. How he would have liked Silver Plane! It is Diana brought up to date. The white, wide, pointed, beautifully smooth, overlapping perianth segments round the deep lemon, saucer-shaped corona, with its edge more pronounced than the interior, make up a Leedsii of very great charm. The Otahuna List of Seedling Daffodils (1921) gives its diameter as 4½ ins. and describes the centre as "pale yellow changing to white." My flower, from quite a small bulb (planted in a pot, May 10th, 1922), is but 3½ ins., with the centre just an inch across, and as yet, after being open over a week, shows no sign of going white, but, on the contrary, it is rather becoming deeper in colour, especially towards the edge. I am very greatly indebted to Mr. Hine, Editor of the *Canterbury Sun*, for a detailed description of the flower by himself, made on the spot, on one of his many visits to Sir Heaton's beautiful garden. It shows what a keen lover of the flower thinks of it, and at the same time it will free me from any charge of exaggeration in what I have written:

"Silver Plane is a peerless flower which has no rivals imported or otherwise in New Zealand. The perianth is very large and solid and of the purest white. The broad cup is very large and flattened to a degree. It is also a fine upstanding garden flower. As a show flower it will always attract attention and has already secured championships in the leading Spring Shows in New Zealand."

I sincerely thank Sir Heaton and Mr. Lowe for their kind gift, which has enabled me to see, in this my lean year, a flower which has a very good chance indeed of becoming world-famous. JOSEPH JACOB.

CROCUSES IN WOODLAND.
The bulbs should be planted without delay.

HERBACEOUS PLANTS and THEIR USES

THE obvious way to use herbaceous plants is in a more or less formal border, and this, it must be confessed, is a quite excellent way. Such a border will front to a lawn or path; if a path, it will be well for the sake of balance of effect to plant herbaceous plants on either hand. We then get what is known as a herbaceous walk. It is not advisable to plant dwarf Roses to balance herbaceous plants. The effect produced is usually unsatisfactory, both as regards "weight" and colouring. A herbaceous walk lends itself admirably to the use of colour schemes, and as, to be satisfactory, the borders should be backed by substantial hedges (or walls), there is no difficulty in fitting such colour gradations into the general garden scheme.

Such borders may be rendered far more effective than they could otherwise be by the introduction of many bulbous plants—May-flowering Tulips, Daffodils, Gladioli (both early and late flowering), Montbretias, Schizostylis and, above all, Lilies. Their effect may be still further enhanced by the employment of rather dwarf shrubs with silvery, greyish or glaucous foliage, such as many of the Southern-woods (*Artemisia*), and Lavender, with such tender and scarcely hardy plants as Dahlias and Chrysanthemums. Certain Grasses may be employed with advantage also, notably some of the species and varieties of *Miscanthus* (*Eulalia*) and that beautiful bronze purple Barley, *Hordeum jubatum*.

If shrubs are useful as foils to herbaceous plants, some of the latter are equally effective and valuable

in the shrubbery. The bulk of herbaceous plants flower when blossom is scarce in the shrubbery and the green background of the shrubs shews to advantage the generally brilliant colouring of the "groundlings." Some plants there are which have a natural grace particularly suitable for the shrubbery. Such are the Torch Lilies (*Kniphofia*), the Delphiniums, the Foxgloves (*Digitalis*), such *Campanulas* as *lactiflora*, *latifolia* and *alliarifolia*, *Bupthalmum* (*Telekia*) *speciosum*, several of the giant Knotweeds (*Polygonum*)—but only in the wild garden, not the cultivated shrubbery—*Spiraea Aruncus*, *S. palmata* and the various forms of the Meadowsweet—*S. Ulmaria*—

roseum, the Evening Primrose (*Oenothera biennis*), *Verbascum* of sorts and *Anemone japonica*, both pink and white.

Such plants as the forms of *Achusa italica* and the beautiful *Cynoglossum amabile* are more sophisticated in outline, but invaluable none the less for the glorious blues they afford. *Salvia virgata nemorosa* is invaluable for half-shady glimpses, and the Azure Sage, *Atriplex Perovskiana*, might be included, but is really sub-shrubby. The same remark will apply to *Romneya*.

Some plants there are which seem made for the paved garden. Delphiniums are especially happy there when of mauve or violet colouring,

though the clear blues look well enough. The deep crimson *Lobelia fulgens* *Queen Victoria* is admirable but in almost all districts needs protection in winter, agreeing in this respect with the florists' *Pentstemons*, which are also good for the same purpose. Some of the large-flowered sorts, if free, are valuable, e.g., *Emile Rodigas*, but, generally speaking, the small-flowered sorts, such as *Newbury Gem* and *Southgate Gem*, are most satisfactory. *Newbury Gem* is hardy enough to stand the winter outdoors in many districts, but if it is to be a real

THE GRACEFUL *CAMPANULA LACTIFLORA ALBA*.

several Goats' Rues, notably *Thalictrum aquilegifolium purpureum*, but also including *T.T. flavum* and *glaucum*, *Lavatera Olbia* and *thuringiaca*, the *Sidalceas* and *Mallows*, *Asphodels* (both white and yellow) and the various Giant *Asphodels* (*Eremuri*), *Achusa myosotidiflora*, *Salvia uliginosa*, such *Michaelmas Daisies* as *Climax*; *Monarda didyma Cambridge Scarlet*, *Lythrum Salicaria*

success needs renewing from cuttings at least every second year. Such things as that invaluable Catmint, *Nepeta Mussini* and *Anthemis Cupaniana* will occur to most people for such a garden, so will the peach-leaved *Campanula*, *C. persicifolia*, *Crimson*, soft pink and soft yellow *Antirrhinums* are all admirable. Though classed officially as hardy perennials, these are almost universally

PENTSTEMON DAYDREAM IN THE SHRUBBERY.

THE LARGE EVENING PRIMROSE, OENOTHERA BIENNIS GRANDIFLORA AMONG PÆONIES.

THE MICHAELMAS DAISY BORDER AT ALDENHAM.

grown as biennials, but it is worth while increasing stock vegetatively for one year to obtain exactitude of shade. Cuttings from seedlings should produce vigorous plants. Cuttings from plants grown from cuttings are, too often, unsatisfactory. The dwarfier sorts, however, when raised from seed may be readily rogued and replaced even when in flower, for they lift and transplant readily. The tall varieties so useful in many situations are less amenable in this respect.

Other plants especially suitable for the paved garden include mauve and soft yellow Violas, Carnations and Pinks—including Allwoodii and Herbertii and, if liked, the new Perpetual Border Carnations—Michaelmas Daisies, particularly Aster acris and the varieties of the Amellus section, many Phloxes, Campanulas lactiflora and carpatia, herbaceous Peonies, Pyrethrum (particularly single ones), Artemisia lactiflora, Thalictrum aquilegifolium purpureum and diptero-carpum and Salvia Tenori. Thalictrum diptero-carpum makes all other members of the genus look not worth growing, but unfortunately its want of vigour in our climate has to be set against its greater refinement when comparing its value with that of the purple form of *T. aquilegifolium*.

Herbaceous plants are often used in gardens to form beds or borders including only one or two or perhaps three genera in each bed, border or walk. A border may, for instance, be planted entirely with Michaelmas Daisies or with Delphiniums, Phloxes, Campanulas, Chrysanthemums, Pentstemons, Antirrhinums or Torch Lilies, or Delphiniums may be associated with Madonna Lilies with or without Nepeta, and the whole will serve as a delightful foil to the reds and pinks of climbing and rambler Roses. Michaelmas Daisies associate well with various Golden Rods (*Solidago*) and Perennial Sunflowers (*Helianthus*) or, again, with Torch Lilies. Chrysanthemums and Michaelmas Daisies are sometimes associated happily together, especially if the lighter yellow and crimson Chrysanthemums are relied upon. Pentstemons and Antirrhinums do not associate well together as a rule, for the lustrous flowering of the Snapdragons kills the "flatter" finish of the Pentstemons. Soft yellow "Snaps" and crimson Pentstemons form a happy exception to this rule, while white Antirrhinums may be used to counterbalance the want of crystal white in the Pentstemon. Though no dead white exists, the palest shades of Pentstemon, whether faintly touched with pink or mauve, are very beautiful and especially attractive in the gloaming when rich colours appear black. The great drawback to these limited associations as to beds and borders of one genus (often one species) is the shortness of time during which they are effective. Take a Phlox border, for instance. A little spring colour may be provided from a foreground of Aubrietia, Arabis or Alyssum associated with spring-flowering bulbs, but with this exception the border must be destitute of colour except for perhaps six weeks of the year, nor will it be at anything approaching its best even for that comparatively short time.

For the not overlarge garden an association of Peonies with Delphiniums and Daffodils is far more desirable as providing a display of colour over a long period, though necessarily the colour effect at any one time is somewhat restricted. That again is where the use of herbaceous plants in the shrubbery scores. Michaelmas Daisies alone produce an effect for a month or so and little of interest for the remainder of the year, but establish in bold drifts of one suitable variety among shrubs, and if careful selection be made, interest can be maintained throughout the year. The close-growing forms, such as the small-flowered ericoides varieties and those intermediate

in type, like *St. Egwin*, are not suitable for such grouping. *Climax laevis*, the late-flowering and typical *vimineus*, the spreading *diffusus* horizontalis and the *Amellus* forms are all excellent, and may be taken as typical of the habits which are desirable in the shrubbery. There are, of course, a multitude of suitable varieties.

Wherever herbaceous plants are grown, very thorough preparation of the ground should be given. Almost without exception fairly rich sweet soil is called for if success is to be obtained. In every case good and deep cultivation prior to

planting will be beneficial. The peculiarities of different genera and species as regards aspect, etc., must always be borne in mind. Phloxes, for instance, like a rich soil with a good moisture content, but they are by no means bog plants. An easterly or westerly aspect suits them better than a site exposed to the direct and sometimes pitiless rays of the sun. Spiraeas also like an abundance of moisture and partial shade. An exception in this regard is *S. Aruncus*, sometimes called the Goat's Beard, which succeeds impartially in light soil or heavy sun or shade.

consider the timber of this tree the most serviceable, superior to that of *P. serotina* and *P. Eugenei*. Free in growth, *P. robusta* quickly forms an attractive tree with large ornamental leaves.

P. generosa is a hybrid of remarkably quick growth raised ten years ago by pollinating *P. angulata* var. *cordata* with pollen of *P. trichocarpa*. Two years later the same cross was repeated at Kew, the resulting trees being known as *P. generosa secunda*. The trees in eight years have grown to a height of 40ft., and it is interesting to record that of three trees which have flowered two are females and one male. There is no difference in their rapid rate of growth, an average of 5ft. for eight years being extremely good in the light sandy soil and atmosphere of Kew. The largest of the leaves measure 13ins. by 11ins.

P. serotina, the Black Italian Poplar, said to be a hybrid between *P. nigra* and *P. monilifera*, is of Continental origin. It is a male tree, and has been very much planted, no doubt because of its free and rapid growth. *P. marilandica* is reputed to be the same parentage but a female tree, as also is a similar hybrid *P. regenerata*,

FAST-GROWING TREES

I.—THE POPLAR

The desire among planters of trees to-day, much more than formerly, is for an immediate effect, or at least in a very short time.

FOR many positions and purposes the Poplars are unrivalled for the following reasons: They are quick-growing and transplant readily when a good size; few, if any, trees thrive better in a variety of soils, positions and climatic conditions in town and country; and they are only rivalled by the Willow in the rapidity and ease with which they may be propagated by cuttings inserted in the open ground.

The cutting up of large estates and the building of smaller houses in suburban and country districts has resulted in a very large demand for quick-growing trees. This may be for one or other object or a combination of several reasons. Fast-growing trees may be required quickly to furnish the pleasure grounds and set off in at least some slight degree the new character of the house. Perhaps more often than not the desire is to screen the house from the road, or quickly to form a barrier to shut out other buildings which overlook or may be an eyesore from the new house.

When there is ample space and abundance of head-room the tall, wide-spreading Poplars may justly claim attention. In cramped positions, with little or no space for overhanging branches, the Lombardy Poplar is usually the most satisfactory. In smoky districts and indifferent soils Poplars can generally be depended upon to give good results.

PROPAGATION.

Poplars and their close allies the Willows are the easiest of all tall-growing trees to increase by cuttings. The normal growth of a Poplar cutting 1ft. long inserted during October or November would be 4ft. to 6ft. the first year in the open ground. If need be Poplar poles 8ft., 10ft., or 12ft. in length with a diameter base of 3ins. or more may be used, placing these in the permanent positions. I can call to mind two instances of Poplar poles being used for pillar Roses which have to-day become a couple of tall Poplar trees. Though Poplars can be quickly raised from seeds, for several reasons, besides the ease with which cuttings root, it is not much practised. To begin with, Poplar trees are usually unisexual, hence more often than not when a mixed collection of Poplars are grown the seedlings prove to be hybrids. This is undoubtedly the reason for so many hybrid Poplars in our gardens to-day. The germinating power of Poplar seeds is both rapid and fleeting. Marked evidence of germination can often be seen within twenty-four hours of gathering and sowing the seeds. On the other hand, Poplar seeds quickly lose their vitality. Several seedling trees of *Populus generosa* (*secunda*) raised in 1914, eight years ago, are now 40ft. in height.

The idea of this note is to review the Poplar for ornamental planting rather than their economical or commercial value. In passing, however,

POPLARS EFFECTIVELY PLANTED BY THE WATERSIDE.

it may be useful to point out the value of quick-growing Poplar as a timber tree. Though a soft wood, there is a ready demand for the wood to-day for such things as packing cases, cotton reels, toys, etc.

Populus trichocarpa, the Black Cottonwood of Western North America, is the fastest growing of the Balsam Poplars and quite one of the most ornamental. A tree planted by the riverside at Kew about twenty years ago now exceeds 60ft. in height. Native trees are sometimes said to reach 200ft. in height. The natural growth of young trees at least, is upright, making a very good screen tree, though it is not advisable to plant as closely as is done with the Lombardy.

P. robusta is a fast-growing hybrid Poplar obtained by crossing *P. angulata* var. *cordata* with *P. Eugenei*. In France some authorities

which originated in Belgium. A frequent nursery name for this group of hybrids is Canadian Poplars.

P. Eugenei is a male hybrid tree which appeared as a chance seedling in the nursery of Messrs. Simon Louis near Metz about ninety years ago. The original tree is 150ft. high. Several trees planted at Kew in 1888 are approaching 100ft. in height. It is said to be a seedling from one of the female Canadian Poplars crossed with pollen from a male Lombardy, hence the strikingly tall pyramidal habit.

The Black Lombardy, *P. nigra* var. *italica* (syn. *pyramidalis*) and the White Lombardy, *P. alba* var. *pyramidalis* (syn. *Bolleana*), are the best trees for close planting to form an effective screen or hedge 20ft., 25ft. or more in height. The distance apart varies according to circumstances. For a close hedge, and to be almost

immediately effective, plant 5ft. apart. As a permanent tall screen 10ft. apart is a good distance; while if space permits of a second row, plant these 8ft. or 10ft. behind the first row, setting the trees alternately between. Being very twiggy trees, they will in a very few years form a most effective screen, even in winter after the leaves have fallen. For town and suburban gardens in particular,

where space is valuable, the Lombardy Poplars are frequently planted, the white (Bolleana) being of the two the more ornamental. Having no overhanging branches the trees give only a minimum of shade. When immediately behind a flower border, trenching the ground within a reasonable distance of the trees every few years does little, if any, harm. A. O.

ON TULIP CULTIVATION IN THE OPEN

IN the year 1907 an excellent book on Daffodils was published by Doubleday, Page and Co. of New York. Its author was Mr. A. M. Kirby, who had, it is very evident from the contents, a wide experience of everything connected with the flower. On page 9 he refers to the small Syndicate of Six which was formed to buy Mr. Engleheart's earliest seedlings. I quote this as an example of his thoroughness and his intimate knowledge of what he was writing about. Hence we feel that the heading of Chapter VIII states a simple fact, "The One Insect and One Disease." The disease was "basal rot" and the insect the daffodil fly "*Merodon equestris*." Nineteen hundred and seven from nineteen hundred and twenty-two leaves fifteen.

Only fifteen years ago, then, that was the happy position in Daffodil land. How different now! When man upsets the balance of Nature he is providing himself, more often than not, with a very big job to put matters right again. The gathering together of plants in a garden is such an upsetting. The interbreeding that creates new varieties is an upsetting. Man is not out of the wood yet in the case of the Daffodil.

Now that the Tulip is increasing year by year in public favour we must not forget that its life under garden conditions in the West is an upsetting of stern Nature. Let us remember the Daffodil and all that has come to pass since the fateful sweltering summer of 1911. We were blind. We did not discern the symptoms of coming trouble, with the melancholy result that there is hardly one garden of any size where that scourge, the *Tylenchus devastatrix* or eelworm, is not. Let us try to be wiser in our cultivation of the Tulip. Once bitten, twice shy. I feel that this article will be well worth writing if only it helps to put lovers of this flower on their guard; if only it makes cultivators keep their eyes open so that they will see when anything is going wrong; if only it prompts them to deal instantly and adequately with the evil. The chief enemy of the Tulip is an insidious fungus known to the learned as *Betrytis parasitica* but colloquially as "fire."

The time when it begins to be very noticeable is about that of flowering. Grey or brown patches are to be seen on the foliage, and the blooms are

TULIPS IN THE PAVED GARDEN.

frequently disfigured as well. Mild attacks do little harm, but when they are severe the bulbs suffer and rot. Most probably many readers have at one time or another been troubled with this "fire." Much can be done at planting-time to avoid it, or at least to minimise it. First, no Tulips should be planted in the same beds or parts of borders where last year it appeared in a virulent form. Secondly, no Tulips should ever be put where they will be exposed to cutting cold winds. If these do not actually originate an attack of "fire," they decidedly aid and abet it. Thirdly, low-lying ground which is subject to spring frosts should if possible be avoided. Fourthly, I am rather inclined to think that in light soil Tulips are more subject to it than in heavier land. Fifthly, late planting helps. Even if it does not do much in this direction, by delaying the appearance of the young foliage above ground it lessens the time that slugs have for feeding on it. Several

times I have noticed how the leaves of early-flowering varieties have been badly eaten when within 4ft. the late-flowering ones have been untouched.

The ideal ground for Tulips is land just on the stiff side, from which a crop of Potatoes has been lifted. We do not have Potato patches on our lawns or in our best flower borders, so all that can be done is to remember the ideal and to make the ground as much like it as one can. Lime is beneficial, it follows that care should be taken to see that there is no deficiency in the soil.

There seems to be a quite unnecessary amount of tribulation about the depth at which Tulip bulbs should be planted. Editors put it down as one of the most necessary ingredients in an article on cultivation. "You know," they tell me, "what to say, how deep to plant and all that sort of thing." Friends continually ask, "Now how deep must we plant the bulbs?" Really Tulips are not very particular. It matters very little if there are 3ins., 4ins., 5ins. or 6ins. of soil over the top of the bulbs. Only last autumn in my garden, as an experiment, some were put in at a depth of 6ins. and some at 9ins., and I could not see any difference between them when they bloomed. What does make a difference is the way the bulbs are treated before they are planted. It is not generally known that by keeping bulbs in a temperature of about 65° to 70° for two or three weeks before they are planted that their flowering is considerably delayed. I saw several large beds of the Rev. H. Ewbank and three or four other varieties the last time I was in Haarlem in Mr. Polman Mooy's ancient Tulip ground at the back of his house in Kleine Hontweg, some of which had been warmed up and some not. The contrast was striking. In each case the treated ones were just expanding and the non-treated ones were going out of flower. It is almost unnecessary to say that this fact may be of considerable use in some gardens. I am sorry I cannot give exact figures of the necessary temperature and the length of time that the bulbs should be in it, but the principle is all right. The origin of the saying that a cat has nine lives is lost in the mists of hoary antiquity. Bedding-out has at least the same number, for it still goes on in many gardens—only priest is writ presbyter. Because of this neo-bedding, late-flowering Tulips are not used as much as they might be for making a big show in the month of May or, in very late parts of our island, in early June. They are in the way when the beds should be filled with their summer occupants. Now it is very easy to circumvent this little difficulty. M. Vianney, the famous priest of Ars, was once asked by a lady who had been in a serious carriage accident what she should do to avoid another. "Madame," said the holy man, "the way is simple. Never ride in a carriage." The difficulty of the late-flowering Tulips might be easily avoided in a similar way by never using any; but this would be something akin to cutting off one's nose to spite one's face. It is wholly unnecessary. If the Tulips are carefully lifted without damaging either the roots or the foliage as soon as they are out of flower and there and then put in an out of the way place by their heels and watered well to settle the soil, they will then ripen off very respectably and will give quite decent flowers the next year.

In writing as I am doing about cultivation I feel as if I were making a fruit salad—so much goes in. I have another ingredient to add. Those who lifted Tulip bulbs this summer will have found in many cases that they have got a whole lot of small bulbs. The hot season of 1921 seems to have made the bulbs split up this summer as they have never done before. I had a long, narrow bed of the early Rose Tendre containing

about 700 to 800 bulbs. I have no end of small bulbs, but I am very doubtful if I will find fifty first-sized in the whole lot. What ought to be done with these? They should be planted at once. The smaller the bulb the sooner it should be put into Mother Earth is a very safe rule to go by. Any bulbs about hazel nut size should be in by the end of September. Smaller ones still, in August; whereas large ones need not be planted until November. It seems to surprise a good many people that small bulbs can be grown into big ones when they are told what I have just written. I suppose they have never stopped to think where or how dealers get the big ones.

"Thank goodness," say the dealers, "even if people do know it, we have generally a good friend at court—Mr. Want-of-Room."

I must bring one more ingredient into the salad—droppers. What are droppers? They are hard-coated little beggars that one finds a good bit lower down in the soil than we would naturally expect them to be when we take up our bulbs. Whence come they? As a rule they are produced by the small offsets of less than hazel nut size. Why the new bulb should come into being in this fashion and not be formed beside the parent bulb is one of the unsolved problems of tuliplom.

As a general rule the smaller the bulb planted the greater the number of droppers. Naturally, they are a bit of a worry at lifting time if we want to get the bed up "clean." Droppers look different to ordinary bulbs. They have a hard skin and a long elongated shape. When they are set they become normal before they are lifted. Those who can read German should get "Das Leben der Tulpe," by Edmund Döring, published in 1910, if they want to learn more about them and also how new bulbs are formed in the ground. Not everyone knows that you say good-bye for ever to a bulb when you plant it. Truly the tulip is *La Fleur Merveilleuse*. JOSEPH JACOB.

THE EVOLUTION OF THE GLADIOLUS—III

The Large-flowered Hybrids.

A YEAR or two ago a serious thought assailed me of scrapping all the large-flowered Gladioli so as to devote concentrated attention to the primulinus hybrids. Then came intimate knowledge of some of the fine new varieties raised in America, and my resolution went the way of those reborn on December 31 of each year of grace.

I think Byron L. Smith and Alton were the founders of this personal renaissance. When first I saw these two flowers I recognised that the large-flowered hybrids had an important mission to fulfil, and also there was the immediate

suggestion of unbounded possibilities of a union between the popular primulinus hybrids and the glorious colour blends of this new race of giant-flowered Gladioli. Of Byron L. Smith I have written before in these pages, and now that the public have had repeated opportunities of seeing it their appreciation has been immediate and conclusive. It has bounded into supreme favour and cannot fail to retain its place for a long time to come. This summer I have listened to many opinions and guesses as to its real colour, but probably the truest value in words is "softest cattleya mauve." But so soft is the shade that

lavender pink might also aptly figure it in the mind if you know the flower. If you do not, no jargon of words will give you its portrait. On the lower segments there is a milky yellow blotch suggestive of moonlight which tones out the petal colour to perfection. Alton is a fine type of the ruffled-flowered Gladiolus. The large circular flowers are rather compactly held on the massive spike, but the colour is soul-satisfying. Described in the catalogue as of finest orange colour, my notes say salmon orange with an intense fiery orange scarlet blotch in the throat, a good blend of warm tones. After the same style is Favourite, of which we have

GLADIOLUS FAVOURITE

GLADIOLUS RARITY.

a picture here; more a self-coloured flower perhaps, and if there is any meaning in a shuffling of the descriptive words, I should call it more orange salmon where the other is salmon orange. The emphasis, I take it, rests with the second word. Some more crinkled ones are Charm, a pure deep rose pink with a deeper, almost red blotch; Glorious, a deep cream with apricot throat; Gypsy Queen, of lovely orange red with just a trace of bluish lavender colour in the edges. I like this variety very much for the purity and intensity of its colour. Major Churcher shewed it well at the International Show in Glasgow in a competitive class where the judging was a bit awry. Humming Bird is somewhat dwarf in growth but with a stiffly held strong spike. The flowers are not so pretty as in some, but it is pleasantly peculiar, a sort of lavender sheen overlying a rather harsh pink shade. The lower segments are almost covered with a deeper and harmonising blotch. Æolian is very handsome, having plenty of flowers open at once and the colour very telling, pure salmon rose with distinct bluish margin. Adoration is practically a self of dark Lincoln red deepening in the throat, and has about six flowers open at a time. Then there is Crinkles, intensely ruffled and of pleasing peach blossom pink, but the flowers are not very large. It is fine for vase decoration, however. E. J. Shaylor is particularly good, and is better known in this country than most of these ruffled sorts. Two years ago it gained the A.M. at Vincent Square and at that time attracted much notice. It is a deep rose pink, forming a bold spike and is a good grower. I do not like purple-coloured Gladioli as a rule, but Purple Glory is a thing apart, perhaps because it is not purple. Anyway it arrests the attention at once with its giant ruffled flowers and enormous spike. The colour is elusive of description, but I imagine it to be an intense violet maroon with great, almost black, blotches. It is a pity it takes 12s. 6d. to purchase a bulb of this one, for it is a powerful help to the exhibitor and cannot but capture the judge's eye.

Some of the plain-petalled Gladioli from America are even more astounding in colour than the ruffled sorts. Among the novelties introduced this year John J. Pirrie is quite remarkable as an entirely fresh break. The flowers are beautifully formed and of the most extraordinary slaty mauve colour adorned with a rich crimson blotch. No other Gladiolus within my ken has a complexion anything near this. Marshal Foch, not to be confounded with Hopman's Dutch variety of the same name, is another 1922 novelty and a decided acquisition. Its giant flowers are brilliant salmon pink of a very fresh shade and many flowers are open at a time, making it valuable for exhibition. Red Fire (A.M., 1922) is the best red Gladiolus of any so far as my experience goes. It has a depth of colour and "fire" seldom seen in a flower, and when more reasonable in price will be in great demand. Several of the 1921 introductions from the U.S.A. have proved very good in our gardens, notably Hollyhock, a remarkably round flower, tinted white with large crimson blotch and so arranged on the spike that it closely resembles the flower it is called after.

Red Copper is a fancy Gladiolus of peculiar colour—dark salmon flaked blush old rose, the lower petals being red and yellow with bluish lines running through. Rarity, of which a good illustration is given, is quite unique, and should become a popular variety. The petals are waxy in substance and smoothness, and of a very delicate pale lavender pink. This is a grand flower of high quality. Tranquil does not seem very happily named, the colour being blood red with a taint white lining at the edges of each petal. The last two might well have

changed names. Rarity would have made a splendid Tranquil, but the latter is too sanguine to be placid.

The yellow Gladiolus seems to take a lot of procuring. There is Kelway's Golden Measure introduced a dozen or more years ago, still listed at the absurd price of 42s. a bulb, a figure I should have grudged for it as a first year novelty. From America comes a new one called Gold and in point of colour it is an improvement on Golden Measure, though not so good a grower. Mr. Herbert Robinson of Huckleley, Leicestershire, has been good enough to send me a new yellow self of his own raising, and this promises to become an extremely useful variety if its constitution proves as good as reported. It is only in the seedling stage yet, having bloomed for the first time last year, but the appearance of the spike certainly indicates vigour and good style of growth, while the colour of the flower itself leaves little to be desired.

Each year I admire the beautiful contrast of colour in Incontestable. I first saw it as shewn by Major Churcher at Vincent Square, and immediately procured it. The large, round, white flowers are perfectly pure except for a big crimson blotch on the two lower segments, sharply defined, no feathering of one colour into the other. Kelway's Painted Lady is very similar, and both are conspicuously beautiful. I should guess that the progenitors of these two varieties were highly coloured for practically every seedling from them is full of colour, scarlet, crimson and deep pink predominating, but all shew something of the wonderful blotch of the parents. We have some extremely beautiful new sorts emanating from this blood. Two moderately priced red ones which ought to be in every collection are Black Pansy, a very dark red with almost black lower segments, and Fire Ribbon, of intense fiery red. The special feature of the latter is that by the time the first flower is open the colour is shewing on the topmost bud, so that the spike resembles a perfect band of glowing colour. Challenger, a very popular Gladiolus in our exhibits this summer, is also, fortunately, not too expensive. It has a huge flower of richest velvety red, practically self, and is a strong-growing plant. The best white for the moderate purse is Lily White, a very pure lily-petalled flower with about six blooms expanded at once on a graceful spike.

One of the strangest of the "fancy" group is Loddia, very fascinating to the lover of the *outré* in flowers. The ground colour is a smoky old rose, and it is overlaid with flakes of smoky blue. Try it on the dinner-table with double Gypsophila or fine Asparagus foliage and your guests will ask you what you mean by it!

Then Romance, that beautiful smooth glowing orange salmon flower with a picotee edge of blue, wonderful under artificial light, and the great Mary Pickford of pastel cream and sulphur yellow, wanted by everyone who sees it, and Scarlet Princeps for a bold group in the border where rich scarlet is wanted, and Villa, the little dark, almost black, Gladiolus. One could go on describing favourites all the time, and the halt has not been told. There is wealth enough in the colours of the modern Gladiolus to enrich the most reckless spendthrift. It is a wealth which, luckily, one cannot amass, but it comes with such prodigality for months in each year—from early May till late November we have them in flower—that it almost seems like a rest to have nothing but the imagination to draw on for inspiration.

To those who cannot afford to form an extensive collection of expensive varieties I would urge again the possibility and the desirability of growing from seed. We have so many exquisite seedlings

here that I dare hardly mention them lest I be suspected of romancing, but in due time they will see the light of criticism and speak for themselves. If you imagine seedling raising to be a slow process think of this. Many of THE GARDEN'S readers grow Border Carnations and other plants whose seeds are sown one year and the flowers enjoyed the following. Well, Gladiolus seed sown in the spring will give you some flowers the same summer and practically all the plants should bloom in the succeeding season. You cannot have results much sooner than that unless you go in for annuals only. Here we get seedlings throwing spikes of twelve, thirteen and fifteen flowers seven months from seed.

J. L. GIBSON.

A MORNING STROLL

I SUPPOSE there never was such a season for late Roses as the present. The blooms have been magnificent and the colour as near perfection as possible. Recently, we have had a few days genial warmth and Nature responds very quickly. To-day, after a foggy morning and a heavy dew, I have been struck with the beauty of various conifers, particularly those with glaucous foliage. Perhaps the most noticeable are *Cedrus atlantica glauca*, *Picea pungens glauca* and *Picea Engelmanni glauca*, the latter being a comparatively rare tree even in good collections. *Abies arizonica*, a variety of *A. lasiocarpa*, is a wonderful colour, shining like silver in the sun.

I was struck with the great beauty of *A. Webbiana*, the long deep coloured leaves of which are of a vivid electric-blue tint beneath. This characteristic is very noticeable in many of the *Piceas* and as the trees grow to some size, sufficient to expose the under part of the leaf, is one of the greatest attractions. I notice a considerable burden of cones on the conifers this year, due no doubt to weather conditions last summer, when there was maturity of a kind seldom seen in this country.

The Yews are fruiting very well and to-day I noted specially the yellow-berried Yew, *Taxus baccata fructu-luteo*, which, with *Taxus Dovastoni* alongside made a very charming combination. Some of the *Junipers* were also very attractive and particularly *Juniperus virginiana glauca*, a very beautiful form of the Red Cedar. *J. Tamariscifolia* and *J. communis* var. *hibernica* were both tinted with a lovely sheen of glaucous tint, while opposite habits of growth formed a wonderful contrast. What a beautiful family is the *Juniper* with all its varieties both upright and recumbent! They have the added merit of growing well on limy soils and are, perhaps, the best conifers for such soils. They are not, however, confined to the lime and in fact with few exceptions seem to thrive almost anywhere. A very beautiful form of *J. Sabina* is var. *horizontalis*, and this seems to thrive specially well on soils lacking in lime.

Another point forced itself upon me in my stroll to-day. The wet weather and conditions generally have produced luxuriant growth on almost all conifers, and I could not help but contrast their present richness of colour and luxuriance of growth with the half starved condition of last summer, and some that were only able to grow inches last year have produced almost as many feet this time. There may be some trouble and disappointment as the colder weather comes on, as many plants will go into the winter in very soft condition. One prays for a touch of real Indian summer which would do a lot towards hardening up the sappy growth, which is the natural consequence upon the moist conditions of the last few weeks.

F. GOMER WATERER.

THE GREAT AUTUMN SHOW

THE new departure of the Royal Horticultural Society in holding a great combined Show early in October was a conspicuous success. As most of our readers are well aware, the custom for some time past has been to hold a Summer Show in the beautiful grounds at Holland Park. This admirably situated ground is no longer available and, in any case, it has long been felt by members of the trade that the Holland Park Show followed too closely upon the Chelsea Show. In their wisdom the Council of the R.H.S. decided to try the experiment of discarding the early summer show and of holding a large representative exhibition which would include the annual competitions for British-grown fruit and vegetables. After a prolonged search the Holland Park Rink Hall was decided upon as the best venue for this new departure. The Show opened on October 3 and closed on October 6. The floor area of this hall is approximately four times that of the Vincent Square building, and there is also a convenient gallery. Large as was this space, it was taxed to the utmost.

Previously to the opening of the Show there was no question as to the quantity and quality of the exhibition, which was all that could be desired. The only question which concerned the Council was that of attendance, but any fears entertained were soon dissipated, for a long queue of visitors awaited the opening hour and the large hall was soon filled almost to overflowing; in fact, for a couple of hours or so it was uncomfortably filled.

When viewed from the near gallery the general appearance of the exhibits was especially good, the bright colour was very fascinating. The principal exhibits were magnificent collections of fruit and vegetables, trees and shrubs in their full autumn beauty of foliage and berries, Roses, Carnations, Dahlias and Michaelmas Daisies.

ROSES.

Seldom, if ever, have Roses been shewn in such quantities and great beauty during October as on the present occasion. Not only were the blooms fresh and very good, but there was a marked absence of mildew on the foliage. Mr. Elisha J. Hicks was particularly successful in his method of arrangement. In the arches of such varieties as Mrs. Henry Stevens, Mme. Butterfly, Climbing Lady Hillingdon and Ophelia, the blooms stopped at just the right place and gave way to the foliage and berries. In his large stands Mr. Hicks displayed such highly decorative sorts as Isobel, Covent Garden, Padre, Mrs. Elisha Hicks and

Mrs. C. Lamplough. The large vase of the brilliant hips of *Rosa Fargesii* found many admirers.

Roses of recent introduction were fairly plentiful and amply illustrated their autumn value. In the exhibit by Messrs. Alex. Dickson and Sons there were generous masses of Lady Inchiquin and Betty Uprichard, almost, if not quite, as beautiful as at Regents Park in the height of the Rose season. Lulu, Sunstar and Earl Haig were also very handsome. The Hybrid Musk Nur Mahal, which received a certificate at the Autumn Rose Show, was again shewn in great quantity by the Rev. J. H. Pemberton and was here equally as

Plymouth, Mrs. Henry Stevens and Alex. Hill Gray are the names of only a few so well-shewn. *Souvenir de Claudius Pernet* has been shewn in great beauty on several occasions this year and at the Holland Hall was staged by Messrs. Jarnan and Co. and Mr. George Prince. *Niphetos* has become almost a scarce variety of late years, so its appearance in the collection by Mr. John Mittock was particularly welcome and, while losing none of their pale beauty, the blooms had the robust appearance of having been grown out of doors. Mr. Mittock also shewed the richly coloured, fragrant *Walter C. Clarke* with *Hadley*, *La Tosca*, *Ophelia* and other sorts. *Hoosier Beauty* and *Hadley* were in good form as shewn by Messrs. Stuart Low and Co., while Messrs. Dobbie and Co. included *Col. Oswald Fitzgerald*, *Lieut. Chauré* and *Christine* in their good collection.

CHRYSANTHEMUMS.

For the most part it was the outdoor varieties that were shewn, though Mr. H. J. Jones in one of his characteristic groups displayed a great number of Japanese blooms of exhibition size. Several of these were unusually early. The largest were *Mona Davis* (a beautiful mauve), *Mrs. G. Lloyd Wigg* (yellow) and *Donatello* (a very bright incurving yellow). His decorative varieties included *October Glow* (rich chestnut), *Pink Delight*, *Pink Protusion* and *Uxbridge Pink*. Of all the small-flowered sorts none was brighter than *Verona*, of which Messrs. Wells and Co. had a large vase of the intense terra-cotta blooms. *Golden Polly*, the pure white *Sanctity*, *Knareborough Yellow*, *Harvester* (of chestnut colouring), *September Glow* and *September Gem* were all of great decorative value.

The massed colours of many outdoor varieties made a great show in the exhibit of Messrs. Keith Luxford and Co. They also had the vivid *Verona*, with *Early Buttercup*, *Lichfield Purple*, the *Pink Marie Masse Golden Polly*, *Uxbridge Pink* and *Framfield White* in delightful sprays. *Normandie*, which is such a valuable hardy variety, was very beautiful in a group arranged by Mr. W. Vandell, and he also shewed the white Mrs. Roots, *Cranfordia* (of fascinating bronzy yellow colouring), *Crimson Pride* (in intense colour), *Le Pactole*, *Horace Martin* and a valuable scarlet sport from *Almirante*.

DAHLIAS.

The gorgeous colours in the many groups of Dahlias were very welcome amid some of the more sombre exhibits. Of the many types on view it was the highly decorative small *Peony*-flowered that attracted most attention, and small wonder, for these are of very useful size—sufficiently large for decorative purposes and yet not so large as to flop about after having been cut a few days. The colours of the newer miniature *Peony*-flowered varieties are most entrancing. Besides the new varieties which have been described in these pages from time to time, Mr. J. T. West shewed *Oriole*, *Floss*, *The Quest*, *Sweetness*, *Winter Sun* and *Lovely* of this type. There

THE NEW EARLY-FLOWERING INCURVED CHRYSANTHEMUM
CISSBURY WHITE.

effective. *Ruth*, of fascinating golden-apricot shading, was a delightful foil to the fragrant crimson novelty. In the collection by Messrs. F. Cant and Co., their large pink Hybrid Tea variety, *Captain F. S. Harvey Cant*, was quite as good as when first shewn at Chelsea last May. The *Queen Alexandra Rose* has been most successful this year and was well shewn here and in the fine stand by Messrs. B. R. Cant and Sons, who also had *Golden Emblem*, *Ophelia* and *Lady Pirrie* in great beauty.

Climbing Mme. Edouard Herriot, which was included by Messrs. C. Prior and Sons in an interesting collection, will scarcely be as popular as the bush variety; it is not nearly so beautiful and is of poor form, but "*Golden Mail*," as Mr. Prince named a charming pale orange yellow sport will probably have a future. In this collection *Tea and Noisette* Roses were especially good. *Lady*

was also an admirable selection of them in an exhibit by Mr. J. B. Riding, who, by the way, is of the decided opinion that these beautiful flowers will be the most popular Dahlias of the near future. He included in a representative collection such sorts as Marcella, Ladybird, Judith, Cato, Gladys Urwin, Tendresse, Picture and Nora Bell, and they were all most charming examples of the type Yellow Pet and the new varieties were also very beautiful in a collection by Mr. Charles Turner, though one associates him more particularly with the dainty little Pompon varieties, of which he had perfect specimens in Mignon, Nerissa, Orpheus, Little Beeswing and many others. Such large Peony-flowered sorts as Liberty, Phidias, Coralie and Sunray provided glowing colours in this collection.

To Messrs. Cheal's exhibit one always turns for the artistic Star Dahlias, and on the present occasion they included Crimson, Autumn, Gattou, Mauve and Horley Stars. Their singles were of fascinating form and wonderful colouring. The old favourite Show and Fancy Dahlias of perfect form and really charming colouring were prominently shown by Messrs. W. Treseder, Limited. The principal varieties were Pandora, Nugget, Nansen and Hon. Mrs. Percy Wyndham.

Exhibition Cactus varieties were the most important in a large collection by Messrs. Carter Page and Co., and the outstanding sorts were Silverhill Park, Princess, Paragon, Border King and Pennant. The Decorative type was also good, particularly such dusky maroon varieties as King Harold, Pharao and Romney. Messrs. Dobbie and Co. have long specialised in the Collarette varieties, and displayed excellent blooms of Tiger, Clyde, Glencoe, Linnet and Onse-

TREES AND SHRUBS.

As one would expect in the autumn, berried trees and shrubs were extensively shown, though it must be confessed they did not make the gorgeous display of colour one would have anticipated. For the most part the lighting of the hall was responsible, but in several instances the wealth of available material was not displayed to the best advantage. This was particularly noticeable in the large circular group from the Hon. Vicary Gibbs, Aldenham Gardens. This had the place of honour in the centre of the hall, and while the individual items were mostly of great value, the arrangement was distinctly uninspiring. Flowering species were represented by branches of *Lepedeza Sieboldii*, *Spartium junceum*, *Spiraea sorbitolia* and the old favourite *Erythrina Crista-galli*. Glowing autumn colour was provided by *Acer japonicum laciniata*, while the most showy berried shrub was *Pyrus firma*. The pure white berries of *Pyrus Aucuparia munda subarabnoides* were very uncommon. Near the outside of this group there was a dwarf plant of *Vitis Brandt* bearing small, clean bunches of Grapes.

A very interesting collection of berried shrubs was arranged by Mr. Sidney Morris, Earlham Hall, and this included fruits and the immense yellow flowers of *Lonicera Hildebrandtii*. These were, of course, grown in a greenhouse, but all the rest were hardy. *Euonymus intermedia*, which may almost be termed an improved *E. europæus*, was particularly well fruited. *Hippophae rhamnoides*, *Cratægus* and *Berberis* in many varieties were well represented. *Berberis* (very well berried), *Cotoneaster Zabelli*, with various conifers and Maples were associated with bold-

habited herbaceous flowers and *Lilium* by Messrs. Wallace and Co.; while Messrs. J. Piper and Sons had *Eleagnus glabra* and other species in their mixed group.

The best arrangement of shrubs was that by Messrs. Hillier and Sons, and they made a group of conifers and another of mixed trees and shrubs very attractive. Many of the cones on such species as *Abies brachyphylla*, *A. arizonica*, *Picea bicolor* and its variety *reflexa*, *Pinus Ayacahuite* and *P. sinensis*. A graceful arrangement was made by Messrs. J. Cheal and Sons, and they displayed *Cratægus yunnanense*, *C. coccinea dentata*, *C. mollis* and *Pyrus discolor* among fruiting shrubs. A young plant of the Maidenhair Tree (*Ginkgo biloba*) was very striking in its rich golden autumn colour. Messrs. Cheal's flowering species included *Eucryphia cordifolia*, *Clerodendron foetidum* and *Buddleia compacta*. A good selection of *Ceanothus*, including *C.C. Ceres*, *Gloire de Versailles* and *floribunda* was displayed by Messrs. Waterer, Sons and Crisp, who also had attractive plants of *Taxus nova aurea*, *T. japonica* and several heavily fruited *Berberis*. The pairs of rounded pea-like fruits of *Descaisnea Fargesii* shown by Mr. G. Keuthe attracted a deal of attention, and he also had a good collection of dwarf shrubs suitable for planting in the rock garden.

Clematis were particularly handsome. Messrs. L. R. Russell, Limited, had great blocks of many varieties all in 5in. pots just as they are despatched. These were excellent plants bearing half a dozen or so beautiful flowers. The most striking varieties were *Lady Neville*, *Lord Neville*, *King Edward VII*, *Gipsy Queen*, *Lady Northcliffe*, *Marie Boisselot* and *Jackmani rubra* of the large-flowered sorts, while the smaller, very profuse

ASTER LITTLE BOY BLUE.

THE BEAUTIFUL MICHAELMAS DAISY BARR'S PINK.

JUDGED THE FINEST EXHIBIT AT THE SHOW, ARRANGED BY MESSRS. BUNYARD AND CO.

Viticella alba luxurians was also admirable. The smallest Clematis at the Show was *C. tangutica obtusiscula* in the collection of Messrs. G. Jackman and Sons, and its quaint, pendulous yellow flowers fascinated many visitors. In Crimson King Messrs. Jackman have a magnificent large-flowered variety. Messrs. Cutbush shewed a large collection of topiary work. The specimens were very well trained.

HARDY PLANTS.

Herbaceous plants formed a much more important part of this late season Show than one would expect. Signs of a wet summer were everywhere, for only in dripping Junes, Julys and Augusts do these herbaceous things keep on growing and flowering as we saw at Holland Park when October was already well established. To walk around and see such Antirrhinums as Chalk Hill Nurseries staged was like looking back to August. So, too, with Mr. Forbes' Pentstemons from far away Hawick, quite reminiscent of a July show we used to know of similar name and now lost to us. Naturally enough, autumn had to make its presence felt in the great array of Michaelmas Daisies and Asters of all descriptions. Speaking of these plants brings to mind the name of Mr. Ernest Ballard, who has done so much for the Aster family, and he had an excellent display of his wares staged on a large floor space. Some of his new Michaelmas Daisies are real acquisitions to the hardy plant border. Snowdrift, Queen of Colwall, Grey Lady, Purple Emperor and Little Boy Blue are particularly meritorious. The last named is dwarf, bushy and extremely floriferous, and is probably the nearest to a real gentian blue yet achieved. A seedling to be called October Dawn struck us as being a new one likely to become very popular. Its colour is mauvy lavender and the plant forms a perfect mass of blossom.

In Mr. Clarence Elliott's stand it was pleasing to see a fine pan of *Primula Juliana* in full flower among a host of Saxifrages and other rock plants, and *Gentiana sino-ornata* was also well flowered.

A prominent exhibit was a large display of seedling Scabious from Messrs. Isaac House and Son. There is quite a wide range of colour in these flowers now, and a lot of the new seedlings

are sensibly self-descriptive, such as Blue King, Mauve Queen, Silver Queen and even Violet Walters, where the Christian name hints the colour. Collarette, Harold and Nellie Dark were also good breaks. Mr. Wells, jun., of Merstham had a great variety of Asters relieved with the more highly coloured Kniphofias and late Oriental Poppies.

A neat little rock garden was put up by the Misses Hopkins, uncrowded, placid and restful to the eye. Quite works of art were the large floor space exhibits of Mr. Amos Perry and Mr. G. Reuthe. The former used Hollyhocks as a centre-piece surrounded by lavish displays of Oriental Poppies, Asters in every imaginable kind and Tritomas. Mr. Reuthe gave additional colour to his collection with a varied selection of Lilies, such as auratum, Henryi and superbum.

Excellent samples of Lupinus, Kniphofias, Delphiniums and Scabious came from Mr. Thomas Carlile of Twyford, and Pentstemons were at their best as staged by Messrs. Cutbush and Son.

Messrs. Rich and Co. of Bath had a really attractive lot of herbaceous plants, very bright being Gaillardia Sunshine and the Helenium Riverton Gem and Riverton Beauty, the former coppery red and the latter lemon with dark eye.

Meritorious exhibits of general herbaceous plants were staged by Messrs. Bakers of Wolverhampton, Messrs. Harkness of Bedale and Messrs. Gibson of Leeming Bar. Perennial Lobelias designated hardy came from Messrs. B. Ladhams, Limited, Southampton, whose hybrids are gradually extending the colour list among these flowers. Mrs. Humbert (salmon rose), Rose Queen, B. Ladhams (crimson), Shirley Beauty (intense fiery crimson), Delight (lavender purple) and Purple King are good examples. A pretty group of dwarf Delphiniums styled No. 1 Sky Blue shewn as a bedder, only some 12ins. high, was staged by Mr. Herbert Vigers of Dartford. Quite a neat feature of the Show was a pretty little formal rock garden exquisitely designed and shewn by Mr. Ernest Dixon of Putney.

The only exhibit of Gladioli was of the excellent seedlings that Messrs. Lowe and Gibson specialise in. These are as yet unnamed, but they include so many of great merit that we anticipate seeing them again next season.

A very uncommon and welcome exhibit was the large quantity of *Lilium auratum* stems sent by Mrs. C. Lemon from Brodrick, Arran, N.B. This generous collection was evidently from bulbs grown in the open air, but there was a great number of large flowers which diffused a most delightful fragrance.

CARNATIONS.

The style of arrangement adopted by Messrs. Allwood Brothers was particularly effective, and served to display to the full the beauties of a very large collection of perpetual-flowering Carnations as well as their free-flowering Allwoodii varieties. Of the latter the bowls and hanging baskets of such as Marion, Joyce, Vera and Betty were delightful. Among the Carnations proper Wivelsfield Apricot (in a jar of dull apricot colour), Wivelsfield Claret, Edward Allwood of intense scarlet colour, the fragrant old rose Mary Allwood and Nikko were perhaps the very best. Pink Carnations were very prominently displayed by Mr. C. Engelmann in his extensive collection, and these included Laddie, Bona, Cupid and the paler Delice. Snowstorm is a very good white, while dazzling colour is provided by Tarzan. Their large White Pearl was a central feature in the group of Carnations arranged by Messrs. Stuart Low and Co., and they also displayed Eileen Low, Reginald Cory and the Rose Pink Enchantress. Many useful sorts, including May Day and Mrs. C. F. Raphael, were shewn by the Preston Hall Nurseries.

ORCHIDS.

While the Orchids are flowers of many seasons, there was ample evidence at Holland Park that their period of perfection was again drawing near. Looking at the gorgeous richness of colouring attained in the modern forms of Cattleyas alone, it is difficult to realise how far the British climate is from the ideal for these plants.

Messrs. Charlesworth of Hayward's Heath included some new varieties in their collection as, for instance, *Oncidioida Medena*, a cross between *Oncidium cheiropherum* and *Cochlidia Noetzhiana*. This has a long spray of small coppery

red flowers shaded heliotrope. *Cattleya Desdemona* gained an award of merit and looked very handsome with its rich mauve petals, old gold throat and deep purple lip. A new *Brasso-Laelio-Cattleya Golden Crown* was awarded a first-class certificate, and had petals and sepals of rich Indian yellow with reddish purple lip and beautifully veined throat. *Roslyn*, a novelty among *Miltonias*, was of blackish chocolate colour tipped greenish yellow, the lower portion of the lip being pure white. This, too, had an award of merit. Many other forms were shewn in the group, which secured a gold medal.

From St. Albans Messrs. Sander brought an interesting *Laelio-Cattleya Gareloch* var. *Vivid*. The petals and sepals are pure mauve, and the labellum of deep reddish purple and rich velvety texture. Here, too, was *Brasso-Cattleya Maroniris* of exquisite soft mauve and the pretty blue *Vanda corulea*. A silver cup for this exhibit.

Sir Jeremiah Coleman, Bart., shewed a well balanced lot of various forms.

Messrs. Flory and Black of Slough shewed *Brasso-Cattleya Olympus* and another called *Viscount Toda*, for which they got an A.M. The latter is a handsome Orchid of soft reddish mauve and rich purple with a wonderful golden throat.

From the North Messrs. Mansell and Hatcher brought some outstanding flowers, notably *Brasso-Cattleya Heatherwood* of soft mauve and nicely veined throat of golden yellow; *Sophro-Laelio-Cattleya Vivid* of peculiar colour blend in which copper, red and purple all play a part. We liked *Cattleya Eleanor* with an exceedingly dark and lustrous lip, a really beautiful flower.

Messrs. Stuart Low and Co. had a very pretty *Laelio-Cattleya* christened *Mrs. Medo*. The petals and sepals are of bright Indian yellow toning down to a brownish yellow margin, the lip being purple red veined with gold.

A very handsome and tastefully constructed floor display by Messrs. J. Cypher and Sons of Cheltenham attracted a good deal of attention. Many beautiful Orchids were cunningly arranged with a background of foliage plants, including highly coloured *Crotons* and the graceful *Jacaranda mimosaefolia*. The quaint butterfly Orchid *Oncidium Papilio major* was here with many others of all classes. One noticed a particularly fine spike of *Cattleya Peetersii alba*, *Odontoglossum Grande*, *Cattleya Elenore* and *Oncidium oblongatum* all very well grown and flowered.

FRUIT.

As was to be expected fruit formed an important item on the menu at Holland Park. Many of the well known fruit growers put up quite sumptuous arrays of tempting ware and it was pleasant to note that much artistry was employed in this form of staging. Messrs. Bunyard's exhibit was not only a great display of fruit, but it was most tastefully put before the visitors, one might almost say beautifully. There is no need to employ the platitude that the produce was well grown; it was indeed passing well grown, but the way in which the highly coloured Apples were utilised with an eye to decoration was a revelation to many people. Baskets, arranged pendant-wise, of Ben's Red, Worcester Pearmain and Lady Sudeley Apples formed a conspicuous centre of almost gaudy colour, cooled off with cunningly entwined foliage of berried *Berberis*. Marshalled around these were generous samples of all the leading varieties of Apples and Pears, notably Grenadier, Lord Derby, Emperor Alexander, Warner's King and the Rev. W. Wilks among the former, and *Marguerite Marillat*, *Buerre Superin*, *Louise Bonne of Jersey*, *Doyenne du Commerce*, *Roosevelt*, *Catillac* and *Double de Guerre* among the latter. This

exhibit gained the Coronation Cup for the best stand in the Show and the special congratulations of the Council of the R.H.S. Opposite was Messrs. Laxton's of Bedford, another exhibit much enhanced by the art of decoration. From this firm one looks for new varieties of hardy fruits, and of these the following were shewn in excellent condition:— Apples: *Lord Lambourne*, a cross between Worcester Pearmain and Jas. Grieve. This is a heavy cropping variety of delightful flavour, in season during October and November. Medium size and well coloured. Laxton's Pearmain and Laxton's Superb have both gained R.H.S. awards. The latter is the freer cropper of the two, a cross between Wyken Pippin and Cox's Orange, and makes free healthy growth. Its flavour is bequeathed from Cox's Orange Pippin, which it much resembles also in outward guise, but its great value over that well known King of Apples is its long season, which extends to March. Laxton's Peerless is a cooking Apple of exceptional quality, in season from October to Christmas. A new Pear, *Buerre Bedford*, a seedling from Marie Louise \times *Durondeau* shewed distinct characteristics of both

Wilks and The Houblon, which were very well shewn. Messrs. Daniel Bros. of Norwich and Messrs. Prior of Colchester were also to the fore with heavily laden dishes of finely grown Apples and Pears.

A new Apple called *Pantia Ralli* was exhibited by Mr. Will Tayler of Godalming and is said to be a very prolific bearer and of good flavour. Mr. Jas. A. Nix of Tilgate, Crawley, carried off the Gordon-Lennox Cup for the best collection of fruit shewn by an amateur and his collection of Apples, Pears, Peaches, Nectarines, Melons, Dessert Plums and Filberts also won him a large silver cup from the R.H.S.

In the competitive classes the chief prize winners were Mr. J. H. Loudon of Wye, Kent, Lord Bessborough, Sir Hy. Webb, Bart., Captain Drummond, Mr. F. C. Stoop and Rev. C. G. Keau.

VEGETABLES.

Never before, do we think, have the R.H.S. had such a magnificent and comprehensive exhibit of vegetables as that arranged by Messrs. Sutton

PART OF MESSRS. SUTTON'S MAGNIFICENT VEGETABLE EXHIBIT.

parents and its melting flesh is well flavoured. This is an October fruit.

Messrs. Bunyard had a further example of their wares on the floor in the centre of the hall. Here was erected an arched trellis on which vines bearing beautiful bunches of Grapes were trained, making a pretty background to pot-grown Fig trees and dishes of Apples, Pears and small fruits. Mr. J. C. Allgrove and Messrs. Rivers of Sawbridgeworth at the west end of the great hall, and the King's Acre Nurseries at the east end, put up fine lots of fruit trees in pots, while other notable stagings of harvested fruits were displayed by Messrs. Stuart Low and Co., the Barnham Nurseries, Messrs. G. G. Whitelegg and Co., of Chislehurst, Mr. Spooner of Hounslow, Mr. R. C. Notcutt and Mr. E. J. Parsons. Fine results of the work carried on at the Rudgwick Fruit School in Sussex were also shewn.

On Messrs. Cheal's stand one was attracted by the two Apples, *Herring's Pippin* and *Ellison's Orange*, comparatively new varieties, also *Crawley Beauty*, which, with its peculiar colouring of dark green and purple, resembles the older *Enore*. Fruit seems to flourish luxuriantly at the nurseries of Messrs. Waterer, Sons and Crisp, judging by the size and quality of such Apples as *Rev. W.*

and Sons on the present occasion. Occupying 300 sq. ft., were staged 170 dishes of vegetables of the highest quality. We always look forward to the wonderful exhibits emanating from the famous Reading firm, but with the present display they surpassed themselves. It is impossible here to enumerate all the good things on view. However, the following will suffice to shew what a wealth of vegetables were staged. Celery of immense size and excellent quality included *Sutton's Superb Pink* and *Sutton's White Gem*; *Leeks*, *Sutton's Royal Favourite*; *Pea Sutton's Peerless*; magnificent specimens of *Ailsa Craig Onion*; *Cauliflowers*; *Carrots*; *Tomatoes*; *Beans* *Potatoes* and a host of other things. Messrs. Sutton deservedly received the gold medal and congratulations from the Council of the R.H.S.

Another excellent display came from the Hon. Vicary Gibbs (gardener Mr. E. Beckett). Here as usual Mr. Beckett shewed the excellent specimens that we always expect from Aldenham. *Turnips*, *Radishes*, *Endive*, *Brussels Sprouts*, *Tomato Peachblow* and *Onions* were all of first rate quality. This exhibit also received the coveted gold medal.

From Messrs. Dobbie and Co. came an extensive exhibit of *Potatoes*, for which they deservedly received a gold medal. Of tip-top quality and

excellently arranged, this exhibit drew a great deal of attention and admiration. Among the innumerable varieties on view we especially noted Kerr's Pink, King Edward, Katie Glover, The Bishop, Rhoderic Dhu, British Queen and Majestic.

Messrs. Herbert Chapman, Limited, shewed their new Tomato Rotherside, which is of excellent flavour. We also noted the yellow Tomato Orange Sunrise, their seedling stringless climbing Runner Bean and Capsicum Rotherside Mammoth.

Mr. T. H. Jones, Llandilo, won the first prize in the amateur section. He received the Sutton Cup for the best exhibit of vegetables in this section. His carrots were of excellent quality.

Mr. W. H. Myers was awarded a silver-gilt Knightian medal and the R.H.S. Vegetable Cup for the most successful amateur competitor. In the amateur classes the produce shewn was generally of excellent quality.

NEW AND RARE PLANTS.

Aster Novæ-Angliæ Barr's Pink.—In its large size and the general structure of the flowers this exceedingly beautiful Michaelmas Daisy might well be termed a deep rosy-pink counterpart of the lavender-blue Queen of Colwall, which we illustrated on Page 493, but the habit is more robust. It is a splendid variety, quite the best of its type. Award of merit to Messrs. Barr and Sons.

Aster Little Boy Blue.—This is a very decorative, dwarf, bright blue Michaelmas Daisy. The plants form neat little pyramids of semi-double flowers. Award of merit to Mr. Ernest Ballard.

Chrysanthemum Cissbury White.—This is the first new decorative incurved variety which received the first class certificate of the National Chrysanthemum Society a fortnight ago and is described on page 493. Award of merit to Mr. S. Aish.

Kniphofia The Rocket.—This variety is much more graceful than most others of the same size. The long spikes are of bright coral red colour. Award of merit to Messrs. Artindale.

Pyrus Eleyi.—On May 9 last this handsome Crab received an award of merit as a flowering tree, when its vinous red flowers and the purplish tinge on the young foliage was greatly admired. This was illustrated in THE GARDEN, May 20, page 240. It is equally handsome when in fruit. It produces large quantities of long stemmed deep red fruits which are nearly as large as those of John Downie and in shape much like elongated Apples. First class certificate to Mr. R. C. Notcutt.

Viburnum Davidii.—This species, which was introduced by Wilson in 1904, is the most distinct Viburnum in cultivation. It is an evergreen shrub of somewhat spreading habit. The stout, shining three-nerved leaves are about 5 ins. long by 2 ins. wide and its chief beauty lies in these and the bluish shining little oval fruits which followed the stiff cymes of dirty white flowers. Both fruiting and flowering sprays were shewn. Award of merit to Mr. Lionel de Rothschild.

NEW CHRYSANTHEMUMS.

The Floral Committee of the National Chrysanthemum Society met on October 2 and made the following awards to novelties.

Blanche de Poitou.—This free-flowering variety is quite the best of the early white Chrysanthemums. It received an award in 1920 as a large, exceedingly free variety and on the present occasion has the special first class certificate as a market variety. Shewn by Messrs. Wells and Co.

Mme. E. David.—A compact market sized Japanese bloom of rich rosy-lilac colour. There is a suggestion of an old gold centre to the flowers. First class certificate to Messrs. Wells and Co.

September Gem.—This very decorative single yellow Chrysanthemum is suitable either for cultivation as disbudded blooms or in sprays. First class certificate to Messrs. Wells and Co.

NEW DAHLIAS.

The following varieties were selected by the Joint Dahlia Committee for trial at Wisley.

F. G. Bird.—A very showy single Dahlia of vivid scarlet colour. Shewn by Messrs. W. Treseder, Limited.

Hector.—A delightful miniature Paony-flowered variety of starlike form and rich orange-scarlet which changes to purplish crimson. Shewn by Messrs. J. Cheal and Sons.

Lady Hall.—This is a medium-sized Paony-flowered Dahlia of light rosy-mauve colouring. Shewn by Messrs. J. Cheal and Sons.

Mrs. Barrie.—A very pretty miniature Paony-flowered variety. The white petals are lined and lightly flushed with rosy mauve and there is a crimson lake zone to the flowers. Shewn by Messrs. J. Cheal and Sons.

OFFICIAL LIST OF AWARDS.

Coronation Cup to Messrs. G. Bunyard and Co., Limited, for the most meritorious group.

Gordon-Lennox Cup to Mr. J. A. Nix (gardener, Mr. E. Neal), for the most meritorious exhibit of fruit by an amateur.

Sutton Cup to Mr. T. H. Jones for the best collection of vegetables.

R.H.S. Cup for Vegetables to Mr. W. H. Myers for the competitor who secured the greatest number of first prize points.

George Monro Memorial Cup to Mr. G. Miller for the best exhibit of Grapes by an amateur.

National Chrysanthemum Society's piece of plate to Mr. H. J. Jones for the best exhibit of Chrysanthemums.

Wigan Cup to Messrs. Alex. Dickson and Sons for the best exhibit of Roses.

Alpines, etc.—Silver-gilt Flora Medal to Messrs. Clarence Elliott Limited, for alpines. Silver-gilt Banksian Medal to Mr. E. Dixon for small rock gardens. Silver Flora Medals to Messrs. Maxwell and Beale for alpines; and Mr. F. G. Wood for alpines. Silver Banksian Medal to Messrs. Bowell and Skarratt for alpines and herbaceous.

Shrubs.—Large Silver Cup to the Hon. Vicary Gibbs (gardener, Mr. E. Beckett), for shrubs. Small Silver Cups to Messrs. J. Piper and Son for shrubs; and Messrs. L. R. Russell, Limited, for Clematis, etc. Silver-gilt Flora Medals to Messrs. R. W. Wallace and Co., Limited, for shrubs; and Messrs. Waterer, Sons and Crisp for shrubs. Silver-gilt Banksian Medals to Messrs. J. Cheal and Sons for shrubs; Messrs. W. Cutbush and Son for topiary; and Mr. Sydney Morris for shrubs. Silver Flora Medals to Mr. G. Reuthe for shrubs; and Messrs. G. Jackman and Sons for Clematis and herbaceous. Silver-gilt Lindley Medal to Messrs. Hillier and Sons for shrubs. Silver Lindley Medal to the Hon. Vicary Gibbs for shrubs of botanical interest.

Chrysanthemums, etc.—Gold Medal to Mr. H. J. Jones for Chrysanthemums. National Chrysanthemum Society's special piece of plate to Mr. H. J. Jones for Chrysanthemums. Silver-gilt Banksian Medal to Mr. W. Vandell for Chrysanthemums. Silver Floral Medals to Messrs. K. Luxford and Co. for Chrysanthemums; Messrs. W. Wells and Co. for Chrysanthemums; and Mrs. C. Lemon for *Lilium auratum*. Bronze Flora Medal to Mr. J. J. Kettle for Violets.

Dahlias, Carnations, etc.—Gold Medal to Mr. C. Engelmann for Carnations. Large Silver Cup to Messrs. Allwood Brothers for Carnations. Small Silver Cup to Messrs. Dobbie and Co. for

Dahlias, etc. Silver-gilt Banksian Medals to Messrs. Carter Page and Co. for Dahlias, etc.; and Mr. J. B. Riding for Dahlias, etc. Silver Flora Medals to Messrs. Stuart Low and Co. for Carnations; Messrs. W. Treseder, Limited, for Dahlias; and Mr. J. T. West for Dahlias. Silver Banksian Medals to Mr. C. Turner for Dahlias; and Messrs. J. Cheal and Sons for Dahlias. Bronze Flora Medals to the Preston Hall Nurseries and Messrs. Jarman and Co. for Carnations.

Roses.—Gold Medal to Mr. Elisha J. Hicks. Large Silver Cup to Messrs. A. Dickson and Sons, Limited. Small Silver Cup to Mr. G. Prince. Silver-gilt Flora Medal to Mr. J. Mattock. Silver-gilt Banksian Medals to Messrs. B. R. Cant and Sons; and Messrs. F. Cant and Co. Silver Flora Medals to Messrs. Dobbie and Co., Limited; and the Rev. J. H. Pemberton. Silver Banksian Medal to Messrs. D. Prior and Son.

Orchids.—Silver Lindley Medal to Sir Jeremiah Colman, Bart. (gardener, Mr. J. Collier). Gold Medals to Messrs. Charlesworth and Co.; and Messrs. J. Cypher and Sons for foliage and Orchids. Small Silver Cups to Messrs. Sauder and Sons and Messrs. Stuart Low and Co. Silver Flora Medals to Messrs. Flory and Black and Messrs. Mansell and Hatcher.

Greenhouse Flowers, Gladioli, etc.—Small Silver Cups to Messrs. Blackmore and Langdon for Begonias; and Messrs. L. R. Russell, Limited, for stove plants. Silver Flora Medals to Messrs. H. N. Ellison for Cacti and Ferns; and Mr. S. Smith for Cacti. Silver Banksian Medals to Messrs. R. J. Bastin and Sons for Begonias; and Messrs. R. G. Cutbush for *Streptocarpus*. Bronze Flora Medals to the Chalk Hill Nurseries for *Pelargonium*; and Messrs. Lowe and Gibson for *Gladioli*.

Herbaceous.—Silver-gilt Flora Medals to Mr. E. Ballard for Michaelmas Daisies; and Messrs. Amos Perry for perennials and Ferns. Silver-gilt Banksian Medals to Mr. H. J. Jones for Michaelmas Daisies; Mr. W. Wells, jun., for herbaceous; and Messrs. W. Cutbush and Sons for herbaceous, etc. Silver Flora Medals to Messrs. Harkness and Son for herbaceous; Messrs. I. House and Sons for Scabious; Mr. G. Reuthe for herbaceous; Messrs. Rich and Co. for herbaceous; and Mr. E. Scaplehorn for herbaceous. Silver Banksian Medals to Messrs. Bakers, Limited for herbaceous; and Messrs. B. Ludhams, Limited, for Lobelias. Bronze Flora Medals to Mr. T. Carhile for herbaceous; and Messrs. John Forbes for Pentstemons. Silver Lindley Medal to Mr. J. MacDonald for a grass garden.

Fruit (non-competitive groups).—Gold Medal to Messrs. R. C. Notcutt. Large Silver Cup to J. A. Nix, Esq. (gardener, Mr. E. Neal). Small Silver Cups to Messrs. Laxton Brothers and the Rudgwick Fruit School. Silver-gilt Hogg Medals to Messrs. J. Cheal and Sons; Messrs. J. Waterer, Sons and Crisp; Messrs. G. G. Whitelegg and Co.; and the Studley College. Silver Hogg Medals to Mr. E. J. Parsons for Apples; and Messrs. Stuart Low and Co. Bronze Hogg Medals to Mr. H. M. Jones for Apples; and Mr. E. A. Watts.

Fruit and Vegetables (non-competitive groups).—Gold Medals and congratulations to Messrs. G. Bunyard and Co., Limited, for fruit trees and fruit; and Messrs. Sutton and Sons for vegetables. Gold Medals to Mr. J. C. Allgrove for fruit trees in pots; the Hon. Vicary Gibbs for vegetables; and Messrs. Dobbie and Co. for Potatoes. Large Silver Cup to the King's Acre Nurseries for fruit trees in pots and fruit. Small Silver Cup to Messrs. T. Rivers and Sons for fruit trees in pots. Silver Hogg Medal to Messrs. Daniels Brothers, Limited, for fruit trees in pots. Silver Knightian Medal to Messrs. H. Chapman, Limited, for vegetables.

CORRESPONDENCE

ORIENTAL LILIES IN SOUTHERN SCOTLAND.

DURING the last summer atmospheric conditions have been unusually exacting with Lilies, and especially with those in exposed situations that attained a very considerable height. Here, in a Wigtownshire garden the strong winds that have so very frequently visited us this season, accompanied by heavy, devastating rains, drove out of root the grandest representative of *Lilium giganteum* I have ever possessed. Though it afterwards developed its fifteen flowers when planted in a large pot, the leaves had suffered so very severely from atmospheric adversity that their delicate green colour was utterly destroyed. The head gardener at Castle Kennedy tells me that he has during the last three months had many experiences of a similar description. In Logan Gardens, where the shelter is greater, with lofty, protecting hedges, they appear to have escaped, but I had not the privilege of seeing them in bloom. In my own *Lilium* borders, which are much more exposed, the other Lilies I endeavour to cultivate were more fortunate, owing doubtless largely to their smaller foliage and less commanding height, and especially such fine representatives as *Monadelpum Szovitzianum* (which was the first to unfold its graceful, lemon-coloured flowers), *Krameri* (capricious, but a veritable gem), *auratum platyphyllum*, *longiflorum Wilsoni* (which flowered impressively) and the delicately fragrant *speciosum magnificum*.—DAVID R. WILLIAMSON.

A USEFUL PLANT FOR THE ROCK GARDEN.

WHETHER at the front of the mixed border in a widely spreading tuft or amid the rocks and boulders of the alpine garden, *Erigeron glabellus* cannot fail to charm and please. It is at its best from June to August, although you will not find that it is devoid of flowers even as late as the middle of September, for it seems to possess an inexhaustible fund of energy and continues to push up new flower-stems all the while. The habit is very compact and bushy, forming little clumps of low-growing foliage from which spring slender stems of medium-sized, very perfectly formed daisy-like flowers in bright mauve with conspicuous golden centre. The point of the plant is its extended flowering season, and where a very dwarf, neat grower is required you will scarcely do better.—H. W. CANNING-WRIGHT.

A GOOD BORDER PLANT.

ALL the *Rudbeckias* are splendid border plants for "backing up" other flowers, proving their value to the hilt as the autumn days come on, and one of the most distinct of all is the species *subtomentosa*. Though most are very tall growers, this does not exceed 2½ ft., so that it is splendid for the small garden as well as under more spacious conditions, and is excellent for large masses in the medium-sized mixed border. The plants have very stiff, sturdy, upright-growing stems with three parted deep green foliage, which is, in common with the stems, rather hairy. The flowers, though small, are produced with astonishing freedom, and resemble golden yellow Daisies with a purple-brown centre. The *Rudbeckia* is not at all fastidious as to soil, and provided that they have plenty of sun, only one thing must be observed, which is never to allow them to remain without division for more than three

years. *R. subtomentosa* quickly makes a fine clump, but this does not mean that it will continue to do so indefinitely. The reverse is true and, unless the whole is lifted bodily, split up into smaller pieces and the ground—into which they are to be returned—well dug and manured, deterioration will set in and the flowers become smaller and less in number.—HAVELOCK.

YUCCA GLORIOSA BY THE SEA.

I WENT down to the East Coast, Skegness in fact, ten days ago to spend a short holiday and was surprised to find blooming in a friend's garden a *Yucca*, within 200 yds. of the waves. Unfortunately it was rather past its best, but nevertheless I took a photograph of it, which I enclose, thinking that it may be of some interest, owing to the plant being so exposed to the elements. Some idea of the growth may be gained from the fact that the lady standing beside it is 6 ft. in

YUCCA GLORIOSA WITHIN TWO HUNDRED YARDS OF THE SEA.

height. It has been planted as far as I can tell you about twelve years and has not flowered before. A glimpse of the sea may just be seen in the background of the photograph.—ERIC B. FRECKINGHAM.

A LATE-FLOWERING CRANESBILL.

UNLIKE most of its kind, *Geranium Wallichianum* is a late bloomer, a species of rare beauty and one that is a robust and long-lived perennial. In habit it is a sprawling, semi-prostrate plant that enjoys the support of a neighbour upon which it may rest its long, trailing red-tinted stems and bluntly-lobed leaves. The blossoms often appear at midsummer, though the usual date is towards the end of July, and an abundant yield is maintained right on without a break into late autumn. These blooms are flat, or saucer-shaped, well over an inch in diameter, and in the typical plant they are a bluish purple with a broad white eye. But in the form or subspecies known as *E. C. Buxton's Variety*, they are, while retaining the white eye, a clear and most

lovely blue, almost rivalling that of *Nemophila insignis*, to whose blossoms they have some resemblance. Another somewhat unique feature of *G. Wallichianum* is its preference for a cool root run and shelter from the hottest sun. In such a situation the flowers are usually larger and the blue of Buxton's variety is, like that of many other blossoms of that colour, seen to better effect. This *Geranium* is quite hardy, sets seed freely and is easily propagated by that means, the seed being sown in the open ground in summer.—J. N. W.

FOR PARTIAL SHADE.

THAT curious Japanese plant, *Kirengeshoma palmata*, still uncommon in gardens, is worthy of a wider appreciation and culture wherever it can be afforded a moderately good and deep loam, not too dry, and, for preference, in partial shade. In such conditions it will soon make an imposing clump, about a yard in height and width, of shining ebony stems, broad and handsome palmate leaves of unusual design, above and beyond which are extended in loose, drooping sprays the quaint yellow flowers. If it never bore the latter, *K. palmata* would be worth a place for its foliage alone, and if it does not expand its petals sufficiently to please some people, others would be content if it never opened them at all, so curiously attractive are the buds, like ivory acorns in cups of highly polished green. *K. palmata* is a first-rate plant for establishing in fairly open woodland where it can make a large mass. Slugs are inordinately fond of its tender shoots as they appear in spring, but beyond that it seldom seems to give any trouble, for, being hardy and of good constitution, it takes care of itself. The flowers appear in August or September, after which the leaves assume brilliant shades of yellow and buff and, with the stems, entirely disappear as winter approaches.—A. T. JOHNSON.

A BEAUTIFUL ROCK PURSLANE.

THOSE who shrink from the glowing magenta tints that predominate in the elegant Rock Purslanes of South America will find nothing to complain of in *Calandrinia grandiflora*, which is an annual that flowers freely in late summer and well into autumn from seed scattered in any warm, gritty soil in May. It makes a bold rosette of smooth fleshy leaves of an attractive glaucous hue veined with reddish purple. Branching flower stems, also in purple, rise above them to the height of a foot, terminating in pendent clusters of poppy-like buds which expand, one at a time, into large and very beautiful flowers, about the size and shape of those of a Welsh Poppy, in a clear, vivid rose. *C. grandiflora* fully deserves to be more widely known. The seed is very cheap and germinates easily.—CAMBRIA.

A GOOD LATE ANNUAL.

OMPHALODES *linifolia* is an annual not often seen in gardens, but it is one that has many good points, among which may be mentioned its long season of flowering, extending from June to November. *O. linifolia* is not a showy plant, but it never fails to arrest attention since its silvery grey leaves and large ice-white flowers on elegant gin. stems have a peculiarly soft effect and make an admirable group among greys and shades of lavender. Culture is easy, all that needs to be done being the scattering of a little seed in the desired spot in April. In many gardens this annual sows itself freely, which means that an October sowing may be made in any light soil with every prospect of early bloom the following summer.—W.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Maincrops of Carrot and Beetroot may be lifted as soon as they shew signs that growth is finished. The lifting of these maincrops in good time is especially necessary on cold, heavy land, as such ground tends to much coarseness in the Beetroot and causes splitting of many roots among Carrots. Should these crops have to be stored outside, use plenty of sharp sand among the roots to minimise the losses from rotting.

Seakale crowns required for autumn forcing are not nearly in such a favourable state of ripeness as may be wished for. The plants have made growth in abundance and crowns required for later use will be all right. To assist those required early to ripen up a little the roots must be fully one-half raised out of the ground so that light and air may reach the crown. In about a fortnight dig them out entirely and give them a week or so on top of the ground to finish off.

Cold Frames not required for propagating any stock or wintering such should all be gradually filled up with young plants of Lettuce and Endive to be growing on for future use. Frames containing any such plants of Cauliflowers, Parsley, etc., should have the surface soil lightly moved occasionally and receive an abundance of air.

The Flower Garden.

Lawns and Verges.—The time to put away the mowing machine can only be decided by the person on the spot. This autumn has been remarkable for the vigour and constancy of the growth of grass in whatever position it may happen to be, and late mowing is absolutely necessary if neatness and general appearance are to be kept up. About this time, in the lesser well dressed portions of grounds and among groups of deciduous trees, the scythe should be used so that the leaves a little later on may be more easily and quickly collected. Verges, too, may soon, in the majority of cases, receive their last trimming.

The Hardy Fruit Garden.

Root-Pruning.—This is a most important operation, and may briefly be explained as one carried out with the aim of increasing fruitfulness. The next six weeks is the most favourable period for the work, and although it is often extremely difficult to see to all matters at the most favourable moment when so many jobs are all waiting, still it is worth a great effort to get it through during the time mentioned if possible, for plenty of fresh roots then get moving before winter. The actual work consists in taking out a trench several feet away from the stem of the tree and carrying out suggestions generally as advised for indoor Peaches, etc.—see issue September 30. It may be advisable to add that should such pruning have been decided upon for a very large tree, it may be wise to be satisfied with doing half way round this season and watch results.

Fruit Under Glass.

Early Vines.—Pruning-time will soon be here, both for plants in pots and those growing in borders. With this operation looming directly ahead an examination should be made at once of the fitness or otherwise of the wood. There is no comparison between the wonderful early ripening last season and the long drawn out process of this. It may be that where pipe-heat has been cut off for very necessary considerations that the readvent of it judiciously used with an abundance of air may yet tone up the condition of unsatisfactory wood and harden it by the end of the month.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Trenching.—As crops are cleared away and opportunity occurs this very important work should be dealt with. Trenching is specially desirable where the ground is heavy, such land benefiting in no small degree from autumn trenching, and should be thrown up in rough ridges so that disintegration may take place through the

combined influences of frost and sunshine. Choose a dry spell for the work, otherwise the soil cements and requires a good deal of extra labour to put it into working order in spring. Plots trenched in this way prove suitable quarters for deep-rooting plants such as Onions or tap-roots such as Parsnips, Carrots and Beet.

Potatoes.—Complete the lifting of all late varieties as soon as possible. When saving seed of particular sorts reject unshapely tubers or others not in keeping with the type being lifted.

Asparagus.—Immediately the foliage is ripe it should be cut over and the beds thoroughly cleaned of weeds, afterwards applying a top-dressing of well rotted manure.

Globe Artichokes.—A wise precaution in districts where these die off readily during a severe winter is to slip off a number of the side shoots and pot into suitable-sized pots, standing them in a cold frame during the winter. Excessive damp on a heavy soil is at times more detrimental than frost, but suitable protection may be afforded the old plants by placing mounds of ordinary coal ashes round the crowns.

Turnips.—With the exception of Swedes, all Turnips may now be lifted and stored away, as when left longer in the ground they become coarse and split readily.

General Work.—Continue to clear away all spent crops and decaying leaves from the vegetable borders, placing them in the rot-pit, where in time they will become useful manure. This clean up not only rids the garden of an offensive odour but adds to the tidiness of these quarters and clears away the breeding places of innumerable garden pests. Pea sticks should also be stacked away in readiness for another year, discarding those which are of no further use and augmenting the quantity at the first chance during the winter months.

The Hardy Fruit Garden.

Raspberries.—Remove the old fruiting canes from the Raspberry plantation and tie in the necessary quantity of canes for next season's fruiting. Choose stout, well ripened growths, cutting away any superfluous or weak-growing canes.

Planting Currants and Gooseberries.—The middle of this month is quite a good time to plant Red Currants, Black Currants and Gooseberry bushes, as this early planting enables them to emit new roots before the more severe weather sets in. Plant firmly, and should staking be necessary, have it done when planting, as considerable damage may be caused to young plantations by winter storms.

The Flower Garden.

Iris hispanica.—The Spanish Irises thrive best when planted in sandy loam, slightly enriching the ground by the addition of some well decayed manure from a spent hot-bed. Plant the bulbs about 6ins. apart and about 3ins. deep. This popular Iris is esteemed for its lasting qualities when cut, so it is a wise procedure where space permits to plant a good breadth of the most attractive sorts for this purpose. They are also suitable for planting in clumps near the front of the herbaceous or shrubby borders.

Narcissi.—Among the Narcissi varieties such as Emperor, Sir Watkin, Horsfieldi and Victoria make a fine show when planted in groups in the hardy flower borders, giving a fine display before the other occupants have made much growth. When planting, place the bulbs in groups of from ten to twelve, keeping them about 7ins. apart in the group and about 4ins. deep.

Anechusa italica Dropmore.—Few colours in the hardy flower border find more favour than does that of this beautiful Alkanet. Unfortunately, in very cold districts it often dies out during the winter, so that the present is a suitable time to lift and pot up the old roots, standing the pots in a cold frame until the spring. At the same time a quantity of root cuttings should be inserted for fresh stock. If the thong-like roots are cut in lengths of 3ins. and dibbled into cutting boxes, crowns will soon form and produce plants suitable for flowering the following summer.

JAMES McGRAN

(Gardener to Sir Henry H. Honildsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Gladiolus Colvillei and its variety *alba* have for many years been favourite market plants, and they are well worth more general attention from the private grower. Their cultural requirements are simple and they may be grown in pots for standing in the conservatory or simply cultivated for a supply of cut flower. They may be potted at any time now, and will grow well in any good potting compost. The crowns are not large and six of them may be put in a 7in. pot. They are free-rooting plants and I find it an advantage to give them a little extra room at the root. The same remarks apply to the so-called *nanus* section, which includes quite a number of beautiful named varieties, such as *Blushing Bride*, *Fire King*, *Peach Blossom*, *Queen Wilhelmina*, *delicatissima*, *insignis* and *Non plus Ultra*. Like other bulbous plants used for forcing, they should be stood outdoors and the pots covered with ashes until the plants are well rooted. They should then be removed to cold frames, where they may be drawn from as required for forcing purposes, or they may be grown on quite cool, where there is no desire or facilities for forcing them. *G. byzantinus* is a graceful species with rosy purple flowers, which is worthy of more general cultivation in pots for the cool conservatory.

Bravoa geminiflora is a beautiful Mexican plant that should be much more generally grown for the cool or unheated greenhouse. In the south and west it is more or less hardy in light warm soils at the bottom of sunny walls, and it is just such plants that are on the borderline of hardness that are so valuable for cool houses, where little or no fire heat can be used. Dry roots of this plant can generally be purchased during the winter months, when they may be potted and stood in a cold frame. These plants like a light rich loam with the addition of some well decayed leaf soil, and enough coarse sand to keep the whole porous. One root may be placed in a 48, or three in a 6in. pot. It is a slender growing plant some 2ft. in height, and produces its beautiful orange-scarlet flowers in great profusion during July or even earlier when grown in a cool house.

Manettia bicolor is an old favourite which is seldom seen at the present day. It is a slender twining plant which makes a nice specimen if trained over neat supports. It may also be trained over a trellis or used as a roof climber in a small house. This plant is easily propagated by means of cuttings, especially if they can be placed in slight bottom heat, and if propagated at this time good plants may be had for next summer. The scarlet and yellow tubular flowers are produced more or less all the year round.

Moræa.—There are several beautiful species in this genus, but with the exception of *M. iridoides* there are very few of them in cultivation at the present day. They resemble the *Iris* in habit and *M. iridoides* makes a fine specimen if grown in a large pan, but this and the other species are seen at their best when planted out in a well drained border of rich soil in a cool conservatory. In such a situation these plants will throw up their slender wiry flower stems to a height of some 3ft. or 4ft. The flowers are very fugitive, but are produced in succession over a long period. Most cultivators make the mistake of cutting away the flower stems, ignorant of the fact that they remain green and produce flowers for several years.

Maricas somewhat resemble *Moræa* and the best known species are *corulea*, *gracilis* and *Northiana*. Although they are generally supposed to require stove treatment I have found them do quite well in the ordinary heated greenhouse, and like *Moræa* they are seen to best advantage when planted out in well drained borders.

Cannas and other plants such as *Crinum*, *Agapanthus* and specimen *Hydrangeas* that have been standing outdoors after flowering, should now be placed indoors for the winter. *Canna* may be turned out of their pots and after shortening the shoots, stored in any cool building from which frost can be excluded. I find they keep much better if they are not allowed to become too dry. They keep splendidly under a stage on a earthen floor in a cold greenhouse. *Agapanthus* may be kept in a shed, but as they are really evergreen, it is really much better if they can be given a light position in a cold greenhouse. Large specimen *Fuchsias* and *Hydrangeas* can be safely wintered in a dry shed. *Fuchsias* will stand the winter without water, but *Hydrangeas* should not be dried off to the same extent and if standing on an earthen floor they will generally get enough moisture to bring them through the winter.

J. COUTTS.

Royal Botanic Gardens, Kew.

Dahlia Conference.—The National Dahlia Society has arranged a Conference to be held in the Lecture Room at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on October 17, commencing at 4.30 p.m. Sir Frederick Keeble, K.B.E., F.R.S., has promised to preside, and papers for discussion will be read by Mr. T. Hay, Regent's Park, on "Dahlias for Parks and Gardens," and by Mr. J. T. West, Brentwood, on "Exhibiting Dahlias." There is no charge for admission and everyone interested in Dahlias is invited to attend.

A New Lawn Mower.—The Editor has received for trial, through Messrs. A. W. Gamage, Limited, the well known Holborn firm, a specimen of the new "Qualcast" mower, which is intended to supplant the American side-wheel mowers now so popular in this country. The machine is light to handle and cuts well and closely, while the grass box and delivery plate are entirely satisfactory, whereas with the usual American machine they are ornamental rather than useful. This really excellent machine is manufactured by the Derwent Foundry Company, Derby, who are already turning out 1,000 machines per week.

ANSWERS TO CORRESPONDENTS

QUESTIONS AND ANSWERS.—All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant.

FLOWER GARDEN.

FLOWERING PLANTS FOR SHADY PLACES (B. T. T., Staffordshire).—Annuals generally are not to be recommended for shady places. The most suitable perennials

include German Irises, Anemone japonica and varieties, Funkias, Aquilegias, Campanula lactiflora, Dodecatheon Meadia elegans, Epigaea repens, Epimedium niveum, Helianthus varieties (if the shade is not too dense), Hellebores, Heterocallis varieties, Hepatica triloba, Mezasa cordifolia, Saponaria othenticalis fl. pl., Symphytum officinale and Trillium grandiflorum (in a moist soil).

JAPANESE IRISES (Folsted).—Although these plants do well under boggy conditions, we are inclined to the opinion that they are not likely to be very successful in a zinc tank unless measures are taken to shade the sides during hot, sunny weather and to provide some drainage.

MILDEW ON IRISES AND TULIP QUERY (M. K., Norfolk).—The best time to dust or spray plants affected with fungi is immediately the attack commences. As the lime which has been used is, apparently, ineffective, we suggest spraying with potassium permanganate, which may be obtained in the form of crystals that readily dissolve in cold water. A pale rose red solution should be made and the spray should be as mist-like as possible. If the Tulips have been grown well, they will not necessarily be "blind" next year. It must be remembered that, generally, it is only full-sized, well ripened bulbs that produce flowers. During the season of growth the bulbs that are not flowering should be encouraged to develop good, firm bulbs by being watered with weak liquid manure.

TREES AND SHRUBS.

PRUNING CLEMATISES ("Bismarck").—The varieties named (Lady Northcliffe and Mme. le Comte) belong to the Jackmani section, and will give a good show of flower if they are pruned hard back in the early spring.

AZALEAS NOT FLOWERING (Folsted).—We assume that it is the Ghent and Molles varieties that are alluded to. Generally these would not flower so freely the second year as when first planted, but if due attention is paid, particularly in the matter of removing the old flower-heads as soon as they have faded, they should flower well afterwards. But our correspondent must remember that last summer's drought was especially trying to all shrubs. As the Azaleas are planted in a made-up bed of peat and leaf-mould, the fact of there being lime in the natural soil should have no effect.

CLEARING SHRUBBERY FOR REPLANTING (R. E. B., S.W.5).—If the Laurels have been established for any length of time, the shallow, sandy soil will require a considerable amount of enriching to render it suitable for more ornamental shrubs and spring bulbs. After the Laurels have been grubbed up the site should be dug two spits deep if possible, incorporating a liberal quantity of any natural manure, leaf-mould and old potting soil that may be available. The shady portion will require different sorts of shrubs, and in this respect our correspondent will no doubt derive assistance and suggestions from the article on the subject in THE GARDEN dated

September 30, 1922. We suggest that as much planting as possible be done this autumn rather than wait three months as apparently is intended.

FRUIT GARDEN.

PRUNING BISMARCK APPLE ("Bismarck").—Although this variety, like many others, does on occasion fruit at the tips of unpruned branches, it is not one of the relatively few that will fruit only in this manner. The best fruits will be obtained by pruning in the ordinary manner so as to induce the formation of fruit-spurs, the leading shoots on bush or standard trees being cut back to from four to eight buds, according to their vigour. In the small garden Bismarck may well be grown as a cordon.

MISCELLANEOUS.

INSECT FOR IDENTIFICATION (G. G., Clacton-on-Sea).—Larva of death's head moth (Acherontia atropus).

IMPROVING GROUND BENEATH ELM TREES (M. C., Oxon).—If the Elm trees are at all luxuriant, the summer shade will prevent much use being made of the ground beneath them unless the trees can be thinned. In addition to this, Elms are great robbers of the soil. If it is practicable, it would be well to dig a trench about 30ins. deep as near to the Elms as may be convenient and sever all the roots met with; this will keep the area free from roots for a time. The ground should then be well dug, and as it is certain to be rather exhausted, it should be improved by adding a considerable quantity of farmyard manure, if this is available, and any old potting soil that may be on hand.

NAMES OF FRUIT.—W. M. W., Thornliebank.—Apples: 1, probably Grantonian (culinary); 2, probably Ecklinville (culinary); 3, probably Royal Late (culinary); 4, probably Wormsley Pippin (culinary); 5, probably Alfriston (culinary); 6, Wellington (culinary); 7, Court of Wick (dessert); 8, probably Lord Derby (culinary). The specimens sent were very poorly developed and the majority were immature, thus making correct identification difficult.—H. W. R., Sussex.—Apples: 1, The Queen; 2, Anne Elizabeth; 3, Charles Ross; 4, Allington Pippin; 5, probably Ecklinville, specimen badly squashed; 6, Pear Beurré Bosc.—N. G. W.—Pears: 1, Bergamotte d'Autonne, dessert, October to December; 2, Triomphe de Vienne, dessert, September; 3, Souvenir du Congrès, dessert, September; 4, Williams's Bon Chrétien, dessert, September.—C. H., Glensford.—Probably Plum Yellow Myrobalan, specimen badly squashed.—G. Y., Brough.—1, Foster's Seedling; 2, Cathead; 3, probably Albury Park Nonsuch (specimen badly scabbed); 4, Gold Medal; 5, Worcester Pearmain; 6, Lemon Pippin; 7, Bleheim Orange; 8, Allington Pippin; 9, probably Prince Edward (specimen badly bruised); 10, Napoleon; 11, Duke of Devonshire; 12, Monarch.—N. G. W.—Apples: 1, Lord Derby; 2, Warner's King; 3, Ben's Red.

SALE OF BUSINESS.

Wm. PAUL & SON, Waltham Cross, Ltd., beg to give notice that they have disposed of their Nursery at Waltham Cross, together with the stock and goodwill of their business, to Mr. W. E. CHAPLIN, of Waltham Cross, to whom all orders and enquiries should be addressed.

All accounts due to Wm. PAUL & SON, WALTHAM CROSS, LTD., for goods supplied up to September 30th, 1922, should be paid to them at their registered address as below:—

Paul's Nursery, Nursery Road,
Loughton, Essex.

2nd October, 1922.

HARDY PLANTS TO REPLACE BEDDING

The time has come and the season to put hardy plants into position for next year's display.

THERE are numbers of people who object to "bedding-out" plants because, as generally employed, they offend their sense of taste. Even when a better selection is made and the colour effect harmonises they do not like them, chiefly because of the memories they stir of innumerable bedding schemes which were banal at the best and exceedingly offensive at the worst! The objection of most, however, is on the ground of expense. Since the war there are comparatively few gardens which are as well staffed as formerly. The bedding-out being nearest to the house, many have hesitated to give it up because they were uncertain of the extent to which it could be replaced by plantings of hardy perennials reinforced, where desirable, by hardy annuals.

The pictures which illustrate these notes were taken in the formal paved "flower garden" at Gravetye Manor, where this method of furnishing has been in use for a great number of years. Mr. William Robinson was the pioneer in the fight against over-formality, and at Gravetye the veteran author of "The English Flower Garden" (and founder of THE GARDEN) has ample space in which to display the possibilities of more natural methods.

The "flower garden" is quite formal and paved throughout with rectangular paving. (The craze for the comparatively rubbishy crazy paving has received no countenance from Gravetye.) It is as simple in the arrangement of its beds and borders as it possibly can be. There are no elaborate

colour schemes, and the planting is neither specially formal nor studiously natural. A few Roses are included in the scheme, including those two "invaluables" Pharisæer and La Tosca, otherwise a wide variety of plants is grown, though visitors in late summer and autumn cannot fail to be struck with the use which is made of Clematises trained over trellises and archways and also over rough pyramids formed of Larch tops. One of the most striking plants to be seen in this garden is that brilliant blue Houndstongue, *Cynoglossum amabile*. This in some ways resembles the Alkanets (*Achusa*), but is dwarfer and more compact in habit and perhaps more valuable even than those brilliant varieties of *Achusa italica*—Dropmore Variety and Opal. Another plant which is

extremely valuable for such a situation is the dwarf *Achusa myosotidiflora*, which is effective for a very long period.

The bottom illustration on the following page shews a border of *Sedum Ewersi*, a deciduous Stonecrop which is valuable from spring to autumn for its beautiful grey foliage and quite attractive when not in flower. The only other species of *Sedum* really useful for such gardening is *S. spectabile atropurpureum*, which also has interesting and beautiful foliage and in August rather handsome heads of red-purple flowers.

Plants which continue in flower over a long period are especially valuable in beds and borders upon which one is sure to look day by day, and which should therefore always provide interest and beauty. Violas, therefore, are invaluable in soils and situations where they may be expected to do well. The cool shades of colour which they provide are always welcome. *Nepeta Mussini*, as at once long-flowering and charming, will occur to everyone as among the desirables. *Scabiosa caucasica* is a universal favourite for cut flower, and singularly graceful and attractive in the border. It has a reputation for being short-lived—some even call it a biennial—but if divided and replanted every autumn it is perennial enough, its short life if left to itself probably being brought about by what physicians call "auto-intoxication." It probably poisons the soil in which it grows while exhausting the food content.

IN THE "FLOWER GARDEN" AT GRAVETYE MANOR.

THE BRILLIANT BLUE CYNOGLOSSUM AMABILE.

GREY FOLIAGE, ROSE FLOWERS—SEDUM EWERSL.

Both pictures taken at Gravetye.

However that may be, this is certainly a plant of sufficient importance to justify its annual removal and division.

Such small-flowering Pentstemons as Newbury Gem, White Newbury Gem and Southgate Gem, useful everywhere, are specially valuable in the South and South Midlands and, of course, anywhere near a western seaboard, as in such localities they are hardy outdoors. The importance of this ability to survive the winter lies not so much in the saving of labour it involves—though that is considerable—but chiefly in the fact that old-established plants flower earlier than young ones from cuttings of the previous year. As the Pentstemon's glory, like that of the Dahlia, is usually curtailed by frost, early flowering is important. Southgate Gem is larger in flower and taller in habit than Newbury Gem, so that the two varieties hardly compete. White Newbury Gem is less free to flower, but valuable for its colouring. Pink Newbury Gem is of small garden value.

The Lychnis family is rather a difficult one in gardens. Some are bad in habit, some hard of colour and difficult to combine satisfactorily with other plants, but two species both usually found listed under Agrostemma are valuable for our purpose. These are *L. coronaria* Walkeri, with wine red flowers and whitish grey, woolly foliage, and the Rose Campion, *L. Flos Jovis*, also with whitish woolly foliage and rosy flowers. The almost scarlet crimson of *L. chalconica* may be useful in some places.

As already mentioned, Roses of the Hybrid Tea section are grown in prominent positions at Gravetye. Excellent varieties for the purpose are General McArthur, crimson; Joseph Hill, salmon pink; Pharisæer, soft pink; and La Tosca, blush. For continuity of flower and solidity of colouring when seen in mass this section must, however, give way to the Dwarf Polyantha varieties. There is here quite a number of varieties from which a selection may be made, all free-flowering and admirable for producing good colour effect over a lengthy period. Good white Polyantha varieties are Katherine Zeimet and Yvonne Rabier. In pink shades Mrs. W. H. Cutbush, Aschenbrödel and Maman Turbat are good. Rose shades are well represented by Ellen Poulsen and Orleans Rose, and rosy crimson by Jessie and Rödhatte. Most brilliant in colouring is the newer Edith Cavell, not, of course, to be confused with the Hybrid Tea of the same name. Yellow shades are represented by the nankeen yellow Perle d'Or and the golden yellow, shaded crimson Camarienvogel.

Lobelia fulgens Queen Victoria is an invaluable plant, but it will not, unfortunately, stand the winter outdoors except in a few specially favoured localities. As in addition it must, to be satisfactory, have abundant supplies of moisture throughout the summer, it is not welcomed in every garden. The newer soft rose and crimson purple varieties of *L. fulgens* (or, as some would make them, hybrids between *L. fulgens* and *L. syphilitica*) are also valuable, but have the same limitations. *L. syphilitica* itself, whether in blue, white or purple, is not worth garden room. The same may be said of the true (green foliaged) *L. cardinalis*.

The Azure Sage, *Perovskia atriplicifolia*, so much admired by all visitors to Gravetye, is of bushy habit and reaches a height of 3ft. or more. It needs accordingly a fair-sized bed or moderately long stretch of border if it is to be seen to best advantage. The slender spikes of blue flowers are attractive and useful for cutting, but much of the beauty of the plant resides in the silver grey foliage on the elegant slender growths.

To be continued.

TULIP SELECTIONS

The difficulty of choice—Species—A True Tale of Bishop Stubbs—My two-dozen pots—"For Themselves Alone."

CIRCUMSTANCES alter cases. It is not altogether complimentary to tell a person he picks and chooses in an ordinary way, but when a man is known carefully to pick and choose what goes into his garden it is different. He is labelled wise and careful. If he can pick and choose for himself, it is so much the better, but if he is unable to do it, then the next best thing is to get advice from those who can. In what follows I am venturing to make some suggestions which may be helpful to those who are less conversant with the different varieties than I am. They are not the pronouncements of an infallible expert. If the standard of excellence in an English florist's Tulip is so minutely defined and understood that there is very little room indeed for any individual likes and dislikes to come in, there is nothing of the kind to be found in the other branches of the family. You may pay your money and take your choice, whether it be Melicette or Rev. H. Ewbank, whether it be Avis Kennicott or Mrs. Moon, Arizona or Eclipse is purely a personal matter, depending upon individual taste or the requirements of a particular garden. Among the species group it is somewhat different. I remember being told year's ago in Mr. van Tubergen's garden at Haarlem, where I saw the biggest mass of *Fosteriana* that I have ever seen, that they had repeatedly to send travellers to Mid-Asia to collect it and others like *Eichleri* and *linifolia* as they were unable to propagate them in a satisfactory manner at home. Many of them it will be seen are priced at a higher figure than is usual among Tulips that have been an equal number of years in commerce. Take my special favourite, *linifolia*, and compare it with the lily-flowered *Siren*. The first-named has risen and the last named has decreased in value since 1914. The meaning of it is that *Siren* is a good doer and produces plenty of offsets, while *linifolia* is a poor increaser, seldom giving any offsets and depending for increase upon seed, which in turn does not always behave as it should do. I lost all the species I had during the war, with the sole exception of the pretty little yellow and white *deustemon*. "When my ship comes in" I hope to renew them and start once again upon their culture. Meanwhile I would advise a planting of this kindly disposed species in rock gardens in places where it will get plenty of sun. *linifolia* and *Batalinii* as a rule do well in similar positions in

well drained soil, but they do not increase. I am very fond of *prastans*, which, for a species is not a bad doer. Strong bulbs produce several flowers on a stem. They are a solid sealing-wax red from centre to outside. *Kaufmanniana*, I had almost forgotten; I lost it by pure carelessness, for it is a good doer and once planted takes care of itself. It blooms in March and a patch in bright sunshine when the flowers are fully expanded looks exactly as if some Water Lilies had suddenly changed

TULIP JOHN RUSKIN, APRICOT ROSE.

their nature and taken to Mother Earth. Varieties with glorious red splashes of colour on the outside of the petals and a halo of similar colouring round the pale yellow base have been selected and named. *Ryensis* is about the best. I have also seen pure red, pure yellow and pure rosy-yellow forms which, as so frequently happens in the case of "good things," are, unfortunately for the gardener, of great price. *Tulipa persica* makes itself at home and goes on from year to year without any nursing. Well drained sun-bathed pockets in the rock garden might be filled with it. It makes also a good edging to borders. This much must suffice about the species. The task the Editor has set me is to make selections and I am conscious that so far I have rather been sitting on the gate. It is a job to know which to choose. I envy the definiteness of decision once displayed by William Stubbs, the historian-Bishop. Soon after he

became Bishop of Chester he was approached by the then Archdeacon, who said that his brother clergy would like to make him a present of something that he wanted and which would be useful. They had suggested a pastoral staff. "No," said the Bishop, "if they wish to give me something I really want, let them give me a dozen night-shirts!"

These forewords upon the difficulty of choice have taken on, in my own case, something of the nature of hardy perennials. Nature seems to tell them when I am about to begin. Increased knowledge of varieties makes the task no easier. Do not I wish at such times that the only Tulips in existence were Prince of Austria, Teddy and Louis XIV? Is it not Caroline Testout, the Rose, that is called the slave of the garden? Prince of Austria merits that honourable title among early Tulips. Although Mrs. Siddons, the great actress of early Victorian days liked a garden of sombre evergreens, relieved with little but narrow edgings of deep purple Pansies, might she not have admitted the quite dignified Louis XIV? It is beautiful anywhere, but if the garden lover wants only a garden of bright flowers, he must go elsewhere to suit his taste. Teddy would be far more to his mind, although Homer and a very old Darwin which I never can find in any list—Oliver Goldsmith—would put in their claims as brightest among the almost vermilion reds, and Petrus Hondius as a very bright rose, glorious and gay as only roses minus any blue intermixture can be. Passing on to more precise details, I am going to suppose I have two dozen pots, for each of which I want a different variety, some to bloom early and some later. I would get, of the early singles, Rose Duc Van Thol, Vermillion Brilliant, Prince of Austria, Hector, De Wet and the very sweet Jenny. None of these is either white or yellow, because whites and yellows are easily supplied by different Daffodils. Three early doubles would be included, viz., Couronne d'Or (yellow and orange), Salvator Rosa (rose and white), and Safrano (soft primrose). The remaining fifteen pots would be filled with Cottage and Darwin varieties. Of the first named class there would be Emerald Gem, Cassandra, John Ruskin, Orange King, Bronze Queen and Canary Queen. Then to complete my tale of pots I would select from the Darwins, Sweet Lavender, Pride of Haarlem, William Pitt, Massachusetts, Jefferies (very early), Rev. H. Ewbank, Suzon, The Bishop, and for a real dark, Fra Angelico. Perhaps some will be wondering why no mention has been made about growing Parrot Tulips in hanging wire baskets. It is not a very difficult thing to do, but it is too much of the nature of freak gardening for me. The contorted stems which are caused by the frantic efforts of the poor plants not to pass their allotted span standing on their heads rather nauseates me. Lastly and hardest task of all, I pass on to my choice for planting out of doors. Before I disclose the names of the fortunate (?) ones, I must say that nothing in the way of colour schemes or their sympathy or antipathy with regard to other hues than their own; or their special suitability for this room or that wall-paper, or their stature, or their size of bloom has, as far as I am conscious of it, been taken into consideration. "For themselves alone" is my motto. My twelve Cottage and Breeders are Marksmen, Louis XIV, Boadicea, Prince Albert (orange and brown), Prince Charming, Salomon, John Ruskin, elegans alba, Walter T. Ware, Moonlight, Retroflexa and The President. My Darwins are Petrus Hondius, Teddy, William Pitt, Miranda, Clara Butt, Sophrosyne, Euterpe, Ronald Gunn, Duchess of Hohenburg, Pride of Haarlem, Farncombe Sanders and The Bishop. Undoubtedly I would like to have included a few more, but all those mentioned above are very particular favourites.

of mine and there would be a void were any of them to be dropped out. This, I think, accounts for some omissions which many may think strange, Venus, for example. Many new varieties raised from seed in Holland and by the late Walter T.

Ware, are beginning to get over the garden wall. Which will remain? and which will be kicked out? I do not know—one wants to see more of them than I have done to be able to decide.
JOSEPH JACOB.

BORDER CARNATIONS

SELDOM has the weather been more favourable to Carnation layers than during the present season, so that, where reasonably good stock plants were available, plenty of strong, well rooted layers are now ready for treatment. Most of the present-day Border Carnations are decidedly harder than was the case a decade and more ago. As a consequence in many gardens it is possible safely to transfer the layered plants to their flowering quarters. In a great many gardens specially prepared beds are devoted either solely to Carnations or to them associated with some other plant, and especially with Gladioli. This is almost an ideal combination, and such a bed is interesting and beautiful for a considerable period. Others, like the present writer, consider that, while the finest outdoor Carnations are grown in special beds, the Border Carnations may also be grown in the hardy flower border. In this we fully recognise the fact that our method, if practised solely, precludes the making of a collection of Carnations, but this is amply compensated for by the pleasure in coming upon patches of favourite Carnations cheek by jowl with the herbaceous perennials along the front of the border.

However, when growing Carnations in this manner their requirements must always be studied, and it would be courting disappointment and failure simply to plant them and to leave them pretty much to their own devices for several years, just as one does with, say, Michaelmas Daisies. The Carnation is a much more exacting plant, and the ordinary flower border method would soon result in weedy flowers, fewer in number and inferior in attraction to the old-fashioned garden Pinks. As Turner wrote so long ago as in 1550, the Carnation is "made pleasant and sweet by the wits of man and not by nature," so that more perhaps than any other border flower the wits and skill of man are required if the plants are to be enjoyed at their highest perfection, but, of all flowers, the fresh and fragrant Carnation is well worth the little trouble it demands. In the herbaceous border it is quite an easy matter to take out the old soil where the Carnations are to be planted and to replace it with a fresh compost. The ideal Carnation soil is a mellow fibrous loam with a little well rotted cow manure and sufficient coarse sand to keep the whole porous, but this ideal is not always possible of attainment. The rather too heavy soil can always be rendered more

suitable by the addition of old mortar rubble and leaf-mould, while a proportion of turfy loam will greatly improve a light soil. Lime in some form is essential to the well-being of Carnations, and the best and safest method of applying it is in the form of old mortar rubble. A poor soil cannot grow good Carnations, and if, as is too often the case, good loam and suitable organic manure are not available, the lack of plant food must be made good in some other form. At the present season chemical manures are not to be recommended for use on poor soils intended for Carnations, but bone-meal or quarter-inch bones applied at the rate of 4oz. per square yard will yield a valuable supply of plant food.

If a fresh Carnation-bed is being made, as open and airy a site as possible should be selected, and perfect drainage is very essential. The precise space allowed for each plant is a matter for individual consideration, but as a general guide it may be said that where fresh plants are raised or purchased annually from 12ins. to 15ins. will be found a suitable distance, but if the plants are to continue longer an additional 3ins. will be found an advantage. When planting the layers great care must be taken not to plant too deeply—it is better to err on the other side and plant shallowly, because in this case the danger of wind disturbance can be avoided either by staking or by placing three short stakes around each plant. Firm planting is also an important item.

Fancy Carnations are becoming increasingly popular, as befits their manifold charms. As a short selection for the beginner the following sorts may be recommended: Steerforth, as shown by Mr. J. Douglas at the show on July 11

BORDER CARNATION KELSO.

PINK (HERBERTII) GERTRUDE.

FAST - GROWING TREES—II

Having dealt with the Poplar in our last issue, the writer now confines his attention to various quick-growing trees. The following notes should be helpful to intending planters, especially where a screen is needed.

last was the premier white ground fancy, and in Viceroy he had the premier yellow ground fancy. Kelso was also beautiful. The Bride, rosy red markings; John Ridd, yellow, suffused with red; Mona, buff, suffused with pink; Delicia, pink and crimson markings; Mrs. H. L. Hunt, lavender on white ground; Liberté, maroon and crimson on rich yellow; Daisy Walker, rose pink on white ground; Lord Kitchener, bright red on glistening white; and Pasquin, yellow ground edged and flushed with rosy lavender.

Of the many excellent selfs one can recommend such old favourites as Uriah Pike, rich crimson and of great fragrance; Raby Castle, pink; and Elizabeth Shifner, orange buff, with Bookham White; Border Yellow; Dora Blick, orange apricot with a sheen of gold; Fujiyama, intense scarlet; Grey Douglas, deep heliotrope with a sheen of French grey; Gordon Douglas, bright crimson; Duchess of Wellington, lavender; Innocence, pale salmon pink, almost a blush pink; Mrs. A. Brotherton, clove scented, heavily splashed with crimson-purple on white ground; Rosy Morn; and Bookham Clove, a splendid crimson bloom with a delicious fragrance. For fragrance few, if any, sorts can surpass Scarlet Clove, Surrey Clove, Salmon Clove and King of the Cloves.

Besides these Border Carnations proper the newer Perpetual Border Carnations, which Messrs. Allwood Brothers have been shewing so well, are worthy of a place in any garden. The best sorts include Avondale, rich salmon pink; Brilliant, heavily edged and flaked with chocolate on white ground; Highland Lassie, white ground, edged with red; Rosalind, heavily pencilled with red on white ground; Sussex Pink; and Sussex Maid, flaked with rose pink on white ground. The popularity of the hybrid Allwoodii seems to be fully assured.

Like many other very floriferous plants, they succeed best when renewed periodically—each year for preference—either by division or from cuttings. The latter method is preferable. Owing to their long season of flowering they are invaluable for edgings and for underplanting, being especially useful among Delphiniums. That they are no substitute for the Border Carnations Messrs. Allwood would be the first to admit; indeed, the introduction of the "Perpetual Borders" shews that the Hayward's Heath firm are alive to the special beauty of the Border Carnations. Some of the newer varieties of this popular flower shew a distinct advance both as regards form and colouring upon the older and better-known sorts. This is well exemplified in the "May Day" coloured Maud, which is very dwarf and compact of habit. Marion, which is a rose-coloured self, shews more true Pink blood than do many of these hybrids. The flowers are fringed and very fragrant. Nell, on the other hand, shews more of the Perpetual Carnation blood. Peach-pink in colour, it should be valuable for grouping in the herbaceous border, a position for which the vigour of the crossbreds renders them more suitable than the Border Carnations.

For some reason amateurs will confuse or compare these Allwoodii with the Perpetual Pinks sent out by Mr. C. H. Herbert and sometimes called *Herbertii*. These latter have all the perennial character of the Border Carnations, which in some ways they much resemble. They are easily propagated in a similar way, rooting readily from layers, but may not be pulled apart indiscriminately like most of the Allwoodii. Like all the Carnations and Pink family, they are best established in autumn. The variety illustrated (*Gertrude*) is a very good one. Other indispensable sorts include Queen Mary, Model, Red Indian, May Queen and Victory. They are exceeding free flowering and "perpetual" in character. A. C. B.

IN planting the pleasure grounds surrounding a new house, and the renovating of existing plantations, specimen trees on lawns and in the park, the rate of growth of the trees chosen is of necessity of great importance. It is not for us to find fault with the plantings of our ancestors, fifty to one hundred years ago, but rather to introduce variety where and when we can. Few of them could have had any desire for variety in the planting of the grounds and woodlands surrounding their houses. It is quite true to say that many choice exotic trees are of recent introduction, but there are a few old specimen trees scattered over the country proving that some exotic trees were known, but little planted. In the Thames Valley for instance, there are a number of fine old specimens of the Tulip Tree, *Liriodendron tulipifera*, in the Ham, Petersham and Teddington districts.

Next to having vigorous young trees in any scheme of planting, the greatest asset for quick results in the growth of the trees is in the preparation of the ground. The work may take some time and on the surface appear expensive, but it is as well to remember that once planted, at least in the case of large trees, if growth is satisfactory, the ground will probably not be disturbed again in the life of the planter. Hence the necessity to trench the ground some 2ft. deep, with holes 8ft. or 10ft. across for single specimens. Manual labour must be employed to trench the ground when dealing with small plantations and shrubberies, but for large areas steam tractors can be requisitioned.

In dealing with large areas and in small plantations for that matter, the question of planting Larch, Spruce or Douglas Fir among the permanent trees need not be dealt with, except to point out its value in providing shelter for the trees in the early years of growth, and tending to force upright rather than wide-spreading growth.

While most fast-growing trees are deciduous, where they thrive the value of *Thuja plicata* (grown in some gardens and nurseries as *T. gigantea* and *T. Lobbi*), *Cupressus Lawsoniana*, *Picea excelsa* and *Pseudotsuga Douglasii* must not be overlooked. Planted fairly thickly at first and gradually cut out as growth proceeds, these ever-green conifers quickly form a shelter belt or screen of the first importance in any scheme for the laying out of new pleasure grounds.

Acer macrophyllum, the Oregon Maple, as the Latin name suggests, is a large-leaved tree, native of Western North America, where trees 100ft. in height are not uncommon. It grows freely with us from seeds. On a lawn as a specimen tree it is wide-spreading, but in a plantation grows taller in proportion to the spread of the branches. During April the yellow flowers, borne freely in pendulous racemes, are conspicuous. Several varieties of the Norway Maple (*Acer platanoides*) are fast-growing trees and valuable for ornamental planting. *A. p. Reitenbachii* with green leaves in summer which in autumn change to a brilliant red, is one of the most brilliant and reliable trees for its autumn colour. In contrast to this is the variety *Schwedleri*, which has rich red leaves in April and May, these turning green as summer approaches. The Sycamore (*Acer Pseudo-platanus*) is one of the hardiest and best trees for town gardens and poor soils. Few large trees have produced more varieties under cultivation. Of these the variety *erythrocarpum* is one of the most

interesting and attractive, being gay during most seasons from June till autumn, with quantities of red fruits hanging in conspicuous racemes. The Pilgrig Plane is similar in character, for while the fruits are not quite so large, there are more of them in a raceme. *Acer dasycarpum*, the Silver Maple is another fast-growing tree, and as a lawn specimen very attractive when the silvery under-surface of the leaves are seen swaying on the semi-pendulous branchlets in the breeze. This tree is also readily raised from seeds.

In all except the coldest parts of the country the Indian Horse Chestnut (*Aesculus indica*), should be freely planted now that trees are being grown from home-saved seeds. With green foliage of almost tropical luxuriance, and attractive upright panicles of white flowers, which are borne in June and July, it should become one of our most beautiful summer-flowering trees. The double Horse Chestnut is a fast-growing tree, and producing no fruits to tempt the free use of sticks and stones by small boys, is preferable to the common Horse Chestnut for planting in public parks and gardens. For the same reason the hybrid Chestnut *A. plantierensis* (*A. Hippocastanum* × *A. carnea*), with delicate pink blossoms should be considered as a specimen or avenue tree of free growth.

The Tree of Heaven, *Ailanthus glandulosa*, is an attractive pinnate-leaved tree of easy culture and free growth from Northern China. It thrives in towns and is a good tree for street planting. Usually male and female flowers are borne on separate trees. Cuttings made of the thick fleshy roots placed in light soil, or the fibre of a propagating frame, provide an easy method of propagation.

Betula Maximowiczii, the Japanese Birch, is of free and open growth, with large leaves, 6ins. or 7ins. long and 4ins. or 5ins. broad. Native trees reach 100ft. in height and though first introduced to this country less than thirty years ago, trees are growing freely which, with their large leaves and conspicuous female catkins, promise to be a distinct addition to our taller exotic trees.

The Western Catalpa, *Catalpa speciosa*, is perhaps not so well known to many readers as the Indian Bean, *Catalpa bignonioides*, which is one of our best town trees, and the most beautiful large-flowering tree we have during August. *C. speciosa* (syn. *C. cordifolia*) is taller and faster in growth, flowering a fortnight earlier, the individual blossoms larger but not so freely produced. Both trees should be planted, the Western Catalpa in the woodland and plantations, with *C. bignonioides* (syn. *C. syriacifolia*) as a lawn or park specimen tree.

That attractive pinnate-leaved tree, *Cedrela sinensis*, is a native of Northern and Western China. When first introduced it was, and still is, grown in some nurseries as *Ailanthus flavescens*. Known as the Chinese Cedar, a considerable number of trees have been raised during the last twenty years from seeds collected by Mr. E. H. Wilson. Several of these, growing in a rather moist and shady position in the *Rhododendron* dell at Kew, are making excellent growth.

Each succeeding year that beautiful Chinese tree, *Davidia involuerata*, and the closely allied *D. Vilmoriniana*, are increasing in favour with most tree lovers. Vigorous in growth and free-rooting, trees are growing as luxuriant as the Limes (*Tilia*) which they resemble in leaf. Mr. L. A. Dode, the French botanist, described three species, but growing in gardens only two can be

distinguished: *D. involucreta*, with red petioles and veins of the leaves, which are hairy beneath, and *D. Vilmoriniana* (syn. *D. lata*), with green petioles and smooth under-surface. So far, I believe, only the last named has flowered and produced seeds in this country. Though free in growth when they once commence to push, the hard walnut-like seed-lie in the ground sometimes for two years before germination begins to shew.

As an ornamental tree *Juglans nigra*, the Black Walnut of Eastern and Central United States, is much superior and faster in growth than the common Walnut, *J. regia*. A tall, handsome tree up to 100ft., sometimes more in height, it has long pinnate leaves 15ins. to 24ins. in length consisting of thirteen to twenty-one, rarely more, leaflets. There is a very fine specimen of the Black Walnut in the London County Council Park at Marble Hill, Twickenham, and also several good street trees growing in the Kew Road, Richmond.

Of the six or eight of the *Nothofagus* group of Beeches tried in the open in Britain, *Nothofagus obliqua* appears to be the hardiest and fastest growing, its only likely rival being *N. antarctica*, but this does not produce such a clean stem and tall straight growth. Trees raised from seeds at Kew obtained by Mr. Elwes in 1902 (twenty years ago) are now about 50ft

high. In addition to its free growth this Chilean Beech is an elegant and attractive deciduous tree. A valuable timber tree of South America, the Roblé Beech should be worth experimenting with in the West of Scotland as a forestry tree, as it should not be difficult to import seeds.

The Red Oak, *Quercus rubra*, is the best of the American species for general planting in Britain. It is faster in growth than the common Oak, young trees in particular growing vigorously. A deciduous tree up to 100ft. in Eastern North America, the largest tree in Britain recorded by Messrs. Elwes and Henry, is at Pains Hill, 80ft. high with a trunk 10ft. in girth. The large three to five lobed leaves are 8ins. to 10ins. long and 4ins. to 6ins. wide. Though of much less value as a timber tree than the common Oak, the Turkey Oak, *Quercus Cerris* is more ornamental for plantation and landscape planting, besides being faster growing.

In a stiff and moist soil the Willows have few rivals among trees of rapid growth. I place *Salix caprea*, the Blue or Cricket-bat Willow first because of its free and upright growth, together with the value of the wood for cricket bats. For ornamental trees of large size the planter has also *S. Salamonii*, *S. alba*, *S. babylonica* and *S. vitellina*

Three Lime trees, all of free growth, are worthy of extensive planting in preference to the widely grown Common Lime, *Tilia vulgaris*. *T. euchlora* (syn. *T. dasystyla* of nurseries) is a handsome tree with large glossy green leaves, especially notable because so far as I am aware it is "immune" from the aphides which detract so much from the value of Lime trees in general. *T. platyphyllos* forms a large shapely tree of free growth, as also does the pendent Silver Lime, *T. petiolaris*. In the large family of Elm trees two in

A FINE HORSE-CHESTNUT.

particular claim attention because of their fast and vigorous growth. These are the Cornish Elm, *Ulmus stricta* (syn. *U. cornubiensis*) and the Guernsey Elm, *U. Wheatleyi*. While not so distinctly ornamental as many of the trees previously mentioned, in certain soils and positions, less favourable to the growth of choice trees, these Elms would be very valuable. A. O.

[Most readers will prefer the glossy foliage and handsome trunk of the Sweet Chestnut, *Castanea sativa*, to the rather flamboyant leafage and uninteresting bark of the Horse Chestnut. This latter is certainly not a good roadside tree, as the rough leaves gather dust and the whole tree becomes disreputable. The Horse Chestnut has, of course, other good points besides its rapid growth. The partly expanded foliage is pleasing in spring, but the same may be said of many other trees, and the trees are certainly striking when wreathed with blossom. The growth of the Sweet Chestnut varies immensely in different soils and situations. On the Buckinghamshire soil, for example, so famed for its Beeches, the Sweet Chestnut actually grows more quickly than the Horse Chestnut, which hereabouts does not flourish. An avenue of Sweet and Horse

Chestnuts planted alternately at Checkenden Court, in the Buckinghamshire country, but actually in the county of Oxford, illustrates the point well, for the Sweet Chestnuts, which were the smaller when planted, have quite outdistanced their supposed "nurses." It is scarcely necessary to point out the Sweet Chestnuts and Horse Chestnuts are in no way related the one to the other. While writing of the Sweet Chestnut it is permissible to regret that better varieties from the point of view of their fruits are not usually planted. Most of the seedling forms grown here produce "nuts" almost as insignificant as Beech mast. Probably careful selection would provide even seedling plants which would produce in good summers nuts of commercial value. There are, of course, numerous named varieties in commerce, but seedling trees are usually quicker in growth and somewhat more shapely. In 1921 Sweet Chestnuts everywhere cropped heavily, but, with rare exceptions, the produce was practically valueless. On soils where it really flourishes, the Common Birch is admirably quick-growing and on account of its grace and beauty, specially valuable where very limited space can be devoted to the screen, since it helps the screen and provides foreground at the same time. Under favourable conditions the Birch progresses almost as fast as the Lombardy Poplar.—Ed.]

HALF AN HOUR IN MY GARDEN

I HAVE been charmed to-day (September 29) with a few things which seem to be flowering particularly well for so late a period of the season. *Ceanothus Gloire de Versailles*, *George Simon* and others are as good as possible and in the soft light of these autumn days, particularly beautiful. The *Buddleias*, too, are still fine and I noticed a specially well flowered piece of *Caryopteris Mastacanthus*. *Hypericum Moserianum* and *patulum Henryi* made a splendid gleam of yellow in the sunshine; I also noticed a plant of *Berberis Darwinii* full of bloom as if it had mistaken the season.

Hydrangeas still make a good show and the old *Spiræas*, *callosa alba* and *Autony Waterer* side by side with *Weigela Eva Rathke* were a blaze of colour. I was much pleased with a fine plant of *Andromeda (Oxydendron) arborea*, flowering, it is true, somewhat behind its time, but of great beauty. What a pity this tree does not do better in this climate. A contrast to this in size and also out of season is a clump of *Vaccinium Vitis-idaea* in fruit and flower simultaneously. *Laurustinus*, too, is making a good show. I am afraid several of these plants may feel a severe check before long.

The Vegetable Marrows have already been nipped off by ground frost and we may expect at any time now sufficient frost to cut any plants that are too tender for the time of year.

Other plants I noticed to-day in flower were *Abelia sinensis*, quite a number of *Clematises*, *Escallonia*, *Ligustrum Quihoui* with its long and fragrant flowers, and a few flowers were also to be found on *Ligustrum lucidum*. Some of the hardy Heaths are still giving a good show and among them, flowering very well, were *Erica Maweana*, *E. vulgaris Searleii* and *E. vagans alba*, also *Hydrangea quercifolia*, *Spartium junceum* and *Cytisus monspessulanus*. To these may be added several varieties of *Veronicas*, a few blooms of *Magnolias* and some grand spikes of *Yuccas*. Altogether a goodly list of flowering shrubs for the end of September! F. GOMER WATERER.

ALLIUMS IN THE FLOWER GARDEN

ALLIUM is a large genus comprising something like two hundred and fifty species, natives of many parts of the world, but largely represented in Europe. In cultivation they are more commonly seen in the vegetable quarters than in the flower garden, for the genus covers all our Onions, Leeks and Shallots, besides Garlic and Chives. But the Onions of the flower garden should not be neglected, for among them there are many fine things. Probably the best known is the bright yellow *A. Moly*, a really handsome plant flowering in June, closely followed by the tall *A. neapolitanum* with its great white, globular head and important foliage. The species that are good for garden culture cover a wide range of colouring,

for there is the strikingly handsome *A. cernuum*, a Siberian plant with flowers of a good blue on thin stems; the familiar yellow *A. Moly*; several whose colour ranges through rosy red, magenta and purple; the great white *neapolitanum*; and, besides others of white colouring, *A. karataviense*, a native of Central Asia, with short-stemmed spherical heads of bloom and very wide leaves.

The subject of one illustration, *A. angulosum* or some very near species, may be taken as typical of the form and way of flowering of the greater number of the Alliums. By no means the least beautiful is our native wild Garlic (*A. ursinum*), not uncommon in woody places. If it were not for its rank smell that is only too freely given off,

ALLIUM ANGULOSUM OR NEAR SPECIES.

THE WHITE-FLOWERED ALLIUM KARATAVIENSE.

it would be a desirable plant, especially in places where garden joins woodland, for not only is the white bloom attractive, but also the glossy green foliage, much like that of Lily of the Valley, but of a deeper colour and more polished surface.

GERTRUDE JUCKETT

POISONOUS FRUITS AND SEEDS

FROM time to time cases of poisoning occur among human beings and animals which can be traced to eating fruits or seeds of various plants. These cases have sometimes proved fatal, and at others have ended after a few days' sickness with no worse result than an unpleasant remembrance. As there are many plants that bear fruits and seeds of an unwholesome nature, though not necessarily poisonous, it is wise to instil into the minds of children the necessity for leaving unknown berries or seeds alone, this being the only way to safeguard them against possible injury. The case is still fresh in the minds of people of a child being killed by eating Belladonna berries picked from a plant in a Scottish botanic garden. The law subsequently held that the municipal authorities of the city were to blame for exposing a poisonous plant where it would be tampered with, and allowed the parents compensation. That may have been good law, but whether it was common-sense is another matter. Some people *still* think that it is the parent's place to train their children to distinguish between right and wrong, and to curb any tendency they may notice in a child to picking and eating anything that may take his or her fancy. There are many plants that bear unwholesome fruits which are exposed in public parks and gardens, and necessarily so, for they are often very ornamental, but we ought not to expect municipal authorities to discard them because some unprincipled child may pick and eat the fruits; neither should public bodies be expected to take the part of nursemaids.

In the following notes attention is directed to a number of plants which bear fruits or seeds of an unwholesome nature.

Atropa Belladonna.—This is one of the most poisonous plants found wild in Britain, and it is known under the common name of Deadly Nightshade. A valuable drug is obtained from the plant, hence it is cultivated in large quantities by herbalists and is usually to be found in collections of medicinal plants in botanic and other gardens. It is wild in many parts of the country, probably as an escape from cultivation, but it is these wild plants that offer the most serious temptation to children. The plant is herbaceous in character, grows 1½ft. to 2½ft. high, and bears bright, black, attractive fruits, which are extremely poisonous. Potato fruits, usually green in colour and about 1in. in diameter, are produced freely by some varieties; they must not be fed to stock, as they possess poisonous properties. Two plants belonging to the same family, although not strictly poisonous, are unwholesome and may cause trouble in some cases. These are the Bitter-sweet (*Solanum Dulcamara*) and the annual weed *Solanum nigrum*. The former is a climbing plant well known for its masses of rich red berries and purple flowers, while the latter is remarkable for the profusion of its small round berries. People have been known to eat the berries with impunity, whereas in other cases sickness has quickly followed.

Bryony (*Bryonia dioica*), a wild climbing plant belonging to the Cucurbit family, is well known by reason of its rapid growth, small yellow flowers and small round fruits, which are red when ripe.

Fifteen berries eaten by a child have resulted in death. Cherry or Common Laurel, a bush met with in most gardens, bears racemes of bright black fruits which are said to contain prussic acid. They are very juicy, and people might be tempted to utilise them for jelly, but although the cooked juice might not be unwholesome, it would be wise to exclude them from domestic use. The kernels of one kind of Almond are poisonous if eaten in quantity. That is the Bitter Almond (*Prunus Amygdalus* var. *amara*). Fortunately this variety is rarely met with in cultivation in Britain. The kernels of other varieties are wholesome.

Questions are often asked regarding the value of the Caper Spurge (*Euphorbia Lathyris*) as a substitute for capers. The fruits are sometimes utilised for the purpose, but they are extremely dangerous, and if not very carefully prepared may cause serious illness or even death. The plant often appears as a wilding and fruits freely. The genus *Euphorbia* may be regarded as poisonous throughout.

Castor Oil seeds are attractive and not unpalatable, but by eating three or four serious vomiting may occur, while a larger number would probably lead to collapse. Laburnum seeds are decidedly poisonous, and scarcely a year passes without records of sickness or death among children from eating the seeds. Not alone are the seeds poisonous, but the twigs also, and children have been known to become very ill from biting the shoots. The seeds of Broom (*Cytisus scoparius*) and Gorse (*Ulex europaeus*) also possess poisonous properties. Daphnes, too, are poisonous and as the bright red fruits of *Daphne Mezereum* are very showy, children should be warned against their use. Lupins, Henbane, *Lathyrus sativus*, Lords and Ladies (*Arim maculatum*), Black Bryony, Privet, *Rhamnus* and *Euonymus* are other plants bearing more or less attractive fruits which have dangerous qualities and should not be eaten. The outer fleshy part of the Yew seed is not poisonous, but it is probable that the inner hard seed, if eaten, would prove fatal. Juniper berries have strong diuretic properties, and should not be eaten, while the cones of several conifers are doubtfully wholesome. Acorns are often fed to stock, yet stock have been killed by over-indulgence. Injurious effects appear to follow when cattle are suddenly turned into an Oak wood, or park where Oak trees abound, after a heavy fall of Acorns.

Although so many of our common ornamental berries and fruits are unwholesome, there are many others that can be profitably used for culinary purposes. Thus the various Crab Apples make excellent jelly, as also do the Japanese Quinces (*Cydonia japonica* and *C. Maulei*); *Berberis* fruits may also be used for jelly; Sloe fruits, *Vaccinium* berries, the wide range of Rubi, including the Blackberries and wild Raspberries, are wholesome; Rose hips may be turned into jelly; Hawthorn fruits, although not palatable, are not poisonous; while wild Gooseberries are edible but sour.

This list does not include all the unwholesome or wholesome fruits, but it serves to direct attention to a number in each group. W. D.

FORTHCOMING EVENTS.

October 24.—Southampton Chrysanthemum Society's Show (two days).

October 25.—Irish Gardeners' Benefit Society's Meeting.

October 26. Bristol and District Gardeners' Association's Meeting, Wargrave and District Gardeners' Society's Meeting, Hertford Horticultural Society's Annual Show.

GREASE-BANDING FRUIT TREES

THIS is a very important matter, and ought to receive timely attention, which means applying the bands forthwith.

THE CODLIN MOTH—In epitome I will tell readers who have not had any experience of this pest what it is like and how it destroys their crops of Apples. The caterpillar of the codlin moth is responsible for the worm-eaten Apples so plentifully found, alas! in our orchards. Apples found under the trees prematurely coloured are, generally, the ones attacked by the grub and dislodged before their time from the branches. I daresay many cultivators have noticed the cobwebby appearance of the young fruits with the flowers attached in the early summer-time. The moth has laid eggs in the "eye" of the young fruits and when the caterpillars or grubs hatch out—they are varied in colour, being shades of brown and grey—they work their way tunnel-fashion to the centre of the fruit in due course. As the core is the hardest part of the Apple, the grub tunnels past it but close to it, and this causes the core to harden with its pips prematurely, and then the fruit falls early, when the branches are shaken by the wind. The food of the caterpillar is taken from the pips while the grub is inside. Having exhausted its

Grease-banding stops the female crawling past the bands. Many stick on the latter, so that a renewal of the greasing of the bands is necessary at least twice during the winter months. Flannel

APPLYING A BAND WITH PASTE.

SCRAPING THE STEM.

food supply the grub crawls out of the Apple and makes for itself a home on a rough branch under the bark, covering the hole with a web. They thus remain established in the tree when they leave the fruits in good time, but thousands of them fall, with Apples, to the ground, and grease-banding will prevent them again gaining access to the branches.

THE WINTER MOTH—Grease-banding in this case is most efficacious, and must not be neglected. The bands should be put in place forthwith—two to each stem if possible. The female is practically wingless and must crawl up the trunks or supports to gain the branches. They are grey in colour with full, heavy bodies for moths. The caterpillars eat the leaves of other fruit trees as well as Apples. The female winter moths come out from a chrysalis under the trees where they developed from the caterpillars that went to the soil in summer, and crawl up the trees or props and lay their eggs on the branches and buds.

PUTTING ON THE GREASE.

cloths, in my opinion, form the best bands, as this material absorbs the oils or grease and makes it difficult for the moths to pass *under* the bands. The latter should be fixed to the stem or prop at least twice, from the ground and be firmly tied to the stem in two places about 1 in. from the top and bottom of band respectively. Select a comparatively smooth part of the tree trunk for the band, which should be folded twice after greasing, thus enclosing some of the grease. Cart grease with a thin outer smearing of lardline will answer the purpose, the main point being to maintain the bands in a greasy condition. One band will do if it be carefully applied and afterwards attended to. If grease is scarce, tar may be used on the rags wrapped round the stakes and any branch

supports, but tar must not be used on the bare bark. If grease-proof paper is used, as is more usual, care should be taken to see that it makes contact with the trunk of the tree all round, otherwise the moths will crawl between tree

and band. With paper, too, the "grease" employed becomes important. A grease specially prepared for the purpose should be used or one of the excellent non-greasy banding preparations, such as Stictite G. G.

chosen should be suitable for massing, but in my opinion many of our most beautiful shrubs are much more effective when employed as specimens, and in the above list I would mark Nos. 1, 2 and 9 as being notable examples for this purpose.—
CICIL M. BAILEY.

CORRESPONDENCE

THE WIGAN CUP: WHO WON IT?

IN the list of awards made at the R.H.S. Holland Park Rink Show the Wigan Cup is given as being won by Messrs. Alex. Dickson and Sons, and to those who have not heard the story of the events leading up to this I ask your permission to explain. The points are: (1) Who really did win the Wigan Cup? and (2) What is it offered for? I will deal with No. 1. Now if your readers will refer to the list of awards, they will find that my exhibit was placed first—gold medal—and when the award card was sent out, there came the Wigan Cup card, written in as being awarded to me. To my great surprise, when I arrived back from sending out the result to my friends, I found someone had taken away the card. This was very annoying, and I soon found myself at the enquiry office seeking the reason. All I could find out was that I must wait until the secretary had dealt with it, as something was not in order. I cannot understand why the Council could not have made quite sure before sending out the cards and so making me look like an impostor. As regards No. 2, the Wigan Cup is offered (see page 5 of Autumn Schedule *re* Challenge Cups) for the best exhibit of Roses. Even if I am not eligible because I won it in 1921, how can it be said truthfully and fairly that it was given to the best exhibit if held by another exhibit that was placed second. I consider that if I, as the holder, was not eligible, the only fair course would be for the R.H.S. to withhold it. Even Mr. Dickson could not understand the action. To see two cards for this award upon two separate groups and also various papers giving both myself and Messrs. Alex. Dickson and Sons as the winners is ridiculous, and I trust that the R.H.S. will see that this never occurs again. May I ask, why have such stupid conditions? for the only way to keep up the standard of the exhibits and get us all to put out our best is to give all a free hand. If a firm can win each year, let them have what is their just reward.—ELISHA J. HICKS, *Hurst, Berks.*

THE TWELVE BEST SHRUBS.

HERE are twelve shrubs that I should not care to be without. My garden is in North-Eastern Scotland, where late spring frosts are often troublesome. *Spiraea arguta*, *Viburnum tomentosum* var. *plicatum*, *Buddleia variabilis* var. *Veitchiana*, *Ribes sanguineum*, *Deutzia Pride of Rochester*, *Diervilla Abel Carrière*, *Forsythia suspensa*, *Hamamelis mollis*, *Cytisus albus*, to which add *Rhododendrons*, *Azaleas* and *Roses* according to individual taste.—BRODIE OF BRODIE.

IN reply to Mr. G. Harvey (page 507), it is very difficult indeed to recommend the best twelve shrubs without having any clue as to the enquirer's tastes. Some people want a gay garden, pure and simple; some like old friends; others like to study the ways and habits of comparative strangers. There are, however, a number of well tried favourites without which no garden really seems complete, so that few novelties can as a rule be included among the first dozen. The following list would please many people, and the plants mentioned would do well in most gardens:

Early-flowering.—*Hamamelis mollis*, *Pyrus japonica* (red form) and *Magnolia stellata*. Later spring.—*Berberis stenophylla*, *Lilac* (a middle shade), *Rhododendron Ascot Brilliant* (bright red and early) and *Azalea* (choosing one of the late-flowering red or deep pink). Summer.—*Rose Grüss an Teplitz* (or *Rosa Moyesii* if it must be a species), *Philadelphus grandiflorus* (late-flowering Mock

AURATUM LILIES AT HOLLAND PARK SHOW.

Orange), *Spartium junceum* and *Buddleia variabilis magnifica*. Autumn.—*Crataegus Pyracantha* (for its glorious berries).—A. E. W.

AS an occasional contributor to THE GARDEN and in answer to your request for the opinion of readers as to the best twelve flowering shrubs for gardens, I venture to suggest the following: (1) *Eucryphia punctifolia*, (2) *Embothrium coccineum*, (3) *Berberis Darwinii*, (4) *Cytisus praecox sulphurea*, (5) *Rhododendron Pink Pearl*, (6) *Mock Orange* (*Philadelphus*), (7) *Ribes sanguineum*, (8) *Forsythia viridissima*, (9) *Tricuspidaria lanceolata*, (10) *Escallonia Donard Seedling*, (11) *Veronica Gauntletti* and (12) *Lilac*, the variety to be chosen according to the planter's taste as to colour. I should not care to claim that the above are the "best" twelve, but I have every confidence in recommending them as being "very fine." A word of warning may be necessary, as some of the above would not thrive in every district and garden, accordingly I would advise that they should not be planted in quantity until they had been given a good trial—this applies especially to Nos. 1, 2, 9 and 11. Your correspondent G. Harvey mentions that the varieties

have been shown in England. They were brought all the way from Arran in the Clyde (an achievement—sixty stems!). They will not grow in any other soil even on the same island as they do in their present site. They have been established for almost forty years. These Lilies in their native country (Japan) attain only half this size. Some of the largest stems grown measure 8ft. 6ins. high and have as many as forty-two blossoms on one stem!—G. M. A.A.

(Pictures of these Lilies growing outdoors at Ormidale have appeared in THE GARDEN on several occasions.—ED.)

HARDY HYBRID LOBELIAS.

A ONE-FAMILY exhibit always appeals to me. There is the interest born of "fellow feeling"; there is the interest inseparable from every collection of similar but yet different things; and there is the astonishment at seeing what well directed effort has accomplished. Not even Bunyard's fruit or Sutton's vegetables were as interesting to me as the comparatively humble display of seedling Lobelias staged by Mr. B. Ladham of Shirley, Southampton. It was a sort of equivalent to House's well known *Scabiosa caucasica*. My memory

carries me back to some fine Irish raised seedlings that used to appear at shows in the days of long ago, but magnificent as they were they lacked the variety which was to be seen at the "Skating Rink." *Cardinalis*, *fulgens*, *syphilitica* and some of their hybrid forms have been laid under contribution, with the result that we get an array of colours and shades which are both novel and pleasing. The rich reds and crimsons of wide-petalled flowers, arranged in handsome spikes and associated with various greens and maroons in the foliage, are probably fairly familiar. Mr. Ladhams, however, provides, in addition, roses, pinks and purples. Naturally, the varieties are not all equally good, and in some directions improvement may be expected. I made a note of B. Ladhams (bright crimson-scarlet with green foliage), Shirley Beauty (mulberry-red), Mauve Queen and Delight (two good mauves or pale grey-purple) and *carminea* (rose). There is room for improvement especially in the whites and deeper purples, so I hope Mr. Ladhams will persevere in his work.

One wishes there was no difficulty about their cultivation. Mr. Ladhams advocates covering the plants in ashes for the winter, and then in spring dividing the clumps into single crowns and replanting fairly thickly for effect. We used to litt ours in olden days in the autumn and box them, keeping the boxes all winter on the dry side in a cool greenhouse or frost-proof frame. What is the experience of readers?—JOSEPH JACOB.

COLLETIA SPINOSA.

MR. VEITCH of the Royal Nurseries, Exeter, has kindly replied to the enquiry which I made in *THE GARDEN* of September 30 as to the flowering season of *Colletia spinosa*. He informs me that there are two varieties of this species, one flowering in spring, distinguished by the varietal name *infausta*, the other and normal form flowering in autumn. Here we have only the spring-flowering variety.—HERBERT MAXWELL, *Monreith*.

WITH reference to Sir Herbert Maxwell's note on the above-named plant in your issue dated September 30, page 496, I think he will find that the form that flowers with him in early summer has dull pink inflorescences, while in the case of the autumn-flowering form the shrub bears pure white flowers. I have here plants that observe these differences of time of flowering and colour of flower. In other respects the two plants appear identical, so I cannot say whether they are distinct species or only seminal variations.—H. W. GREGG, *South Devon*.

THE GREAT AUTUMN SHOW.

"NOTHING succeeds like success," they say. Certainly the Royal Horticultural Society will, another year, have to find still larger quarters for the Autumn Show. The Skating Rink at Holland Park Road is quite as inadequate for such a Show as Vincent Square proved itself last year. Nothing short of Olympia will suffice, judging by present conditions and the crowd at last Tuesday's Show. By half-past two there was barely standing place in the most favoured divisions of the Show; and as for seeing anything special or talking to a trades representative at his stall, it was not to be thought of—indeed, one might fairly have said: "I can't see wood for trees!" I came away a disappointed man, vowing I would never again pay a 4s. taxi fare for so little profit or pleasure, and for talk—women-talk—of lesser stature it must have been a suffocation rather than a sight. Is it a sign of the times, I wonder, or is it that young ladies are wondrous wise, that I saw so few of them there? Did they feel cut out

by the beauty and complexions of the fruit, and so carefully kept away? I should like to know, for there were masses of elderly ladies and their companions, regiments of stalwart, rosy-cheeked men with elastic step and far-reaching arm. On the other hand, elderly men were comparatively scarce and quite insignificant by the side of their glowing manhood testifying to the health-giving power of the garden life in these strenuous times. But I was most impressed by one thing, and that is the immortality conferred on anyone who has the honour to give his name to a new fruit of outstanding excellence. We all know the fame of the Ribston Pippin, renowned throughout the globe, in Australia, Tasmania and Europe, to say nothing of the continent of America. What, then, will be the fame of the individual after whom is named the huge Lord Derby or the yellow and red striped fruit the Rev. W. Wilks, named after our late good secretary? I did not taste the fruit, of course, but its appearance, size and beauty go for anything. They must hand down to posterity an honoured name that will defy the ages—more lasting than brass or monument. Really, to-day it would be fair for the raiser to say: "If my fruit honours

growth might be observed. The soil is clay, lightened with leaf-mould and road grit, and has received copious waterings in dry spells. The plant appears not to object to light shade, but, like many choice shrubs, it does not like neighbours too near on either side, and a few branches which have had to compete with other shrubs for space are not in a very flourishing condition. It has always flowered earlier than the time mentioned in *THE GARDEN*, varying a little according to the season. April is generally mentioned as the month when its lovely and strongly fragrant flowers may be expected. This spring some pest (probably sparrows) destroyed a number of the flower-buds as they were swelling; next spring it is proposed to spray with quassia as a precaution. This *Viburnum* is said to be difficult to propagate; at least to grow on its own roots, but bud cuttings are said to be satisfactory.—A. E. W.

HYACINTHS IN PANS.

I THINK perhaps the enclosed photograph of Hyacinths grown by an amateur in moss fibre may interest some of your readers who have never tried this method of culture. The bulbs were planted in October and placed in a cellar. They received no artificial heat other than that usual in a dwelling-house, as I have no greenhouse. Nevertheless, they were very beautiful in March, and provided welcome blossom for six weeks.—E. M. I.

WILD FLOWERS AT COUNTRY SHOWS.

YOUR note on the above in the issue of October 7 is a matter well worthy the attention of horticultural societies when considering their schedules for 1923, while much can also be done by donors of special prizes to encourage the exhibiting and classifying of wild flowers at shows. For many years this has been an interesting class at the annual show at Alnwick, Northumberland, where the excellent practice prevails of having all specimens pressed and dried carefully and mounted on white cards, with their common and also

GROWN WITHOUT HEAT.

your name it is I who should rather profit by it." Lord Derby's and Mr. Wilks' names may be as enduring as the Egyptian king Amenophis and his queen Tia; will they not be hieroglyphed on labels as their predecessors are on temple walls?

After struggling in vain for two hours to gain a comfortable look at anything I gave the whole thing up, and when I got outside an enthusiastic policeman said: "Did you ever see such a crowd of motorists? There must be two miles of them, anyway!"—E. H. W.

VIBURNUM CARLESII.

INTENDING growers may like to know that besides the form with pale pink buds there is one in which these as well as the open flowers are white; this is much less attractive, and it is well worth while taking trouble to obtain the first mentioned. In growth this appears to be a very spreading shrub and not very tall growing. It is possible that the habit may be affected by the stock upon which it is worked, but a plant the writer carried home from one of the Royal Horticultural Society's shows in a small pot two and a half years ago is now 4ft. across and not more than 2ft. in height. No attempt has been made at pruning so that the natural

botanical names attached. At the recent show of the society named the first prize was awarded to an excellent collection of 140 specimens. By following this practice the exhibitor had been making up her collection since February, selecting each species as they came into flower, thus enabling a very representative collection of the wild flowers of the district to be shown, and many of these were of very considerable interest, being rare species or varieties not often met with, and which necessitated much searching on the part of the collector. Not only does this make an interesting exhibit, but the exhibitor also gets a thorough grounding in the life-history and habitats of the wild flowers which will doubtless be of much interest and may be of great practical use to them in after years. The same society also encourages the collection of the various wild fruits of the district, and although these have fallen off greatly of late years, one was greatly pleased to see one very fine specimen basket at the recent show, which was well worthy of the many appreciative remarks made about it. The exhibitors in this class use flat baskets, designing and moulding in clay and overlaying the whole surface with the fruits. Excellent results can thus be achieved.—HORRICKS.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Globe Artichokes.—The unused heads of this vegetable, also old and decaying leaves, should be cut away and the plot lightly forked over. This and the removal of any weeds there may be will give the plot a tidy appearance. Where protection is given these plants for winter it had better wait at any rate for another month or so. By removing some of the side growths at this time and placing them in pots of suitable size some useful plants will be available for spring planting. The wintering of the plants potted up can be done in a cold frame.

Autumn Broccoli.—These are turning in well, and cold nights must be watched for. The usual bending over of the large leaves will be sufficient unless the weather gets very cold, in which case lifting them and heeling them in on a warm border or in a pit may be necessary.

The Flower Garden.

Spring-Bedding Plants.—The filling of beds and borders with the various plants which come under this heading will soon claim attention. In the meantime should such beds have been or still be occupied with summer and early autumn plants, an early clearance of them must now be arranged so that a proper preparation of the soil can be carried out and the beds allowed to aerate for a little time before refilling. Heavy land should receive a liberal dressing of burnt refuse and decayed leaves, while if the soil be light a good dressing of cow manure and leaves will be suitable. The actual planting arrangement must naturally be to great extent a matter of individual tastes and requirements. An immense point in favour of a spring display is that a really fine one may be obtained with a very small outlay. A free and judicious use of Wallflowers, Myosotis, Polyanthus, Cheiranthus Allionii, Arabis and Erysimum will give a wonderfully effective return, even without the addition of any bulbs, and it should be noted that each of the plants mentioned are within the range of everyone and can be raised and grown without the aid of artificial heat. Assuming these plants are to be relied upon for spring flowering, the coolest soil should always be allotted to the Polyanthus.

The Hardy Fruit Garden.

Cherries.—Provided suitable aspects can be allowed for this fruit, a good selection of varieties will supply early, mid-season and late gatherings. Where Cherries are appreciated and an annual yield expected, an orchard-house should be used. The extra cost in providing such a structure would be repaid not only by a guaranteed regular crop grown without interference from weather and birds, but because the fruits come finer in size, colour and flavour. The following varieties can be recommended: Black Eagle, Early Rivers, Frogmore, Early Biggareau, Governor Wood, May Duke, Bigarreau and Morello. The last named is the best Cherry for kitchen purposes, does well on a north wall, and is also to be recommended for pyramid or standard work in orchards. As an earlier fruit for kitchen use May Duke can be recommended. In the preparation of the soil a free use of old mortar rubble is beneficial.

Fruit Under Glass.

Late Muscats.—These will require a little extra nursing so that the finish may be as favourable as possible, thus rendering possible the keeping of the berries in a good condition. It is important to see that all superfluous foliage is removed and the hot-water pipes always warm. On favourable days a fairly free circulation of air should be allowed, but rigidly shut out a foggy atmosphere. No hard and fast rules are possible as to a fixed temperature, as this may with benefit be varied according to the structure in which the Vines are growing, large or small. As a general guide do not allow the night temperature to fall below 60° to 65° until the Grapes are ripe, after which gradually drop to 10° less, according to climatic conditions. Ripe, well finished bunches which may have become destitute of leaf covering should not be continuously exposed to direct rays of hot sunshine. If only a few bunches require shading, sheets of tissue paper will be handy, but when a large number has to be seen to the easiest way is to throw an old fruit net over the glass.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Parsley.—Now that sharp frosts are imminent, means should be taken to protect this popular herb so that fresh supplies may be obtained for a lengthened period. Where lack of frame accommodation exists cover the bed with a few wire pea trainers laid on narrow strips of wood about 18 ins. from the ground. This will prove a useful guard for running mats over on frosty evenings, and thus protect the bed. Feathery Spruce branches are also useful for this purpose.

Rhubarb for Early Forcing.—A number of roots of a good forcing variety should be lifted shortly and placed in a corner of the Mushroom-house or other darkened structure where a certain amount of heat and moisture may be obtained. If suitable quarters are available, a dish may be had by Christmas or early in the new year.

The Hardy Fruit Garden.

Root Pruning.—Where this important work has become necessary preparations may now be made so that any over-luxuriant trees may receive the required treatment to reduce rank growth and bring them to a more fruitful state. If the work is undertaken now, more satisfactory results may be expected than when the trees are resting. The fact of the foliage still being on the trees should enable them more readily to overcome the shock of the large roots being removed. They are further induced to push out young fibrous roots more quickly after root pruning is finished. Where the soil has become exhausted or sour it is a wise procedure to mix some good fibrous loam with the ordinary soil before filling in about the roots. In the case of stone fruits lime rubble is also beneficial if the soil in its present state is short of lime. When root pruning is being done the necessary trench should never be opened nearer the tree than 3 ft. The operator should be guided in this matter more by the age of the tree and the spread of the branches than by any set rule.

Strawberries.—Remove any runners which may have formed on young plantations, afterwards running the hoe between the lines so that weeds may be checked. Older beds should have the soil more deeply stirred, after which a generous dressing of half-rotted manure may be applied.

Black Currants.—Bushes of these should never be allowed to become overcrowded in the centre, otherwise the quality of the fruit is poor, the berries being small and "woody" in flavour. As the fruit is produced on the young wood the heads need an annual thinning, and the sooner this is done now the better will it be for the ensuing year's crop. After completing the work of thinning (and removing any unshapely branches) add a surface mulch of good farmyard manure and fork lightly between the rows.

Fruits Under Glass.

Figs.—Thin out any soft or superfluous growths and regulate the short, sturdy shoots essential for next season's crop. In this way more light and air reaches the wood, thus assisting the ripening process.

Vines.—If the wood of the Vines is not thoroughly ripened before the dull, sunless weather sets in, the chance of a profitable crop next year is considerably lessened. Therefore by ventilating freely and keeping a slight touch of warmth in the pipes the ripening process will be hastened. Where it is desirable to clear a vinery of any remaining bunches, these may well be cut now with enough wood attached to allow of their being placed in bottles and stored in an airy fruit-room. Should the borders be dry, see that they are given a thorough watering. The ventilators should be kept open night and day.

The Flower Garden.

Gladioli.—Where early-planted Gladioli show signs of ripening their foliage they should be lifted with stems attached and laid in a cool, airy place more thoroughly to dry off. Before storing for the winter all offsets should be rubbed off and the corms graded according to size.

Roses.—Place a stake to plants that may have made extra long growths this season, otherwise they may sustain damage from the winter storms. Standards should also be examined at this time and the stakes strengthened or renewed where necessary.

JAMES McGRAN

(Gardener to Sir Henry H. Holdsworth, Bart.),
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Lily of the Valley.—As soon as the crowns can be procured they should be potted up. One dozen to eighteen crowns may be put in a 48-sized pot, and after potting plunged outdoors and fully exposed to the weather. This plunging applies to all hardy plants used for forcing purposes, as they all force more readily after being fully exposed to the cold. If Lily of the Valley is required for Christmas, some six weeks should be allowed for forcing, and even more if a high temperature is not at command. This plant will stand a temperature of 75° to 80° if plunged in a warm case, and there are few hardy plants that will stand such a high temperature with impunity. Where one relies on home-grown supplies of this plant for forcing they should be lifted as soon as the foliage turns yellow and has partly died down, selecting the strongest crowns for forcing and reserving the smaller ones for planting fresh beds. For this purpose fresh beds should be made every year, and if the plants are well grown they should be at their best for forcing the third year from planting. When using home-grown plants some cultivators prefer to lift them in turves and fit them into boxes. By this means and not forcing too hard one is assured of a plentiful supply of good foliage to go with the flowers. Other hardy herbaceous plants that may be used for this purpose are Astilbes (both white and rose coloured), Dicentra spectabilis and Solomon's Seal, the latter a most beautiful and graceful plant for the decoration of the cool conservatory. They should all be put into pots suitably sized according to the size of the roots.

Double-Flowered Wallflowers and Canterbury Bells if prepared as advised during July should now be lifted and potted, afterwards standing them in cold frames until such time as they are required. Damp should be guarded against during winter, giving them ample ventilation at all times; in fact, the frame lights should be pulled off whenever the weather conditions are suitable. The ordinary single-flowered varieties may be potted up for the same purpose, and are very useful for furnishing the unheated greenhouse. In a large public garden like Kew, where such common plants are often used for the conservatory, it is surprising how the general public appreciates them when used in this way. Other hardy plants of which I previously advised the use, such as Campanula persicifolia in blue and white, also the variety Telham Beauty, as well as strong roots of Anemone italica Dropmore var., should now be lifted and potted. By using plants of which everyone can grow a supply, one can easily add to the variety of plants used for furnishing the ordinary greenhouse.

Liliums.—Where a stock of Liliums has been used for the conservatory—here I have in mind L.L. regale, Henryi, auratum and speciosum—they should now be examined for repotting. If they are in small pots and are in good condition, with plenty of healthy roots, they should have a shift into a larger-sized pot without disturbing the roots. If in bad condition at the root, they should be turned out and all decaying scales and roots cleaned off, afterwards repotting them in a mixture of good medium loam and flaky leaf-soil, with the addition of plenty of clean coarse sand to keep the whole sweet and porous. Such varieties as root from the stem should only have their pots about three parts full, this to allow for top-dressing when the plants are growing. Liliun longiflorum is now obtainable, and as soon as the bulbs come to hand they should be potted without delay. If this cannot be done at once, they should be laid out in boxes and covered with leaf-soil, as Lily bulbs will suffer if left exposed to the air for any length of time. Where seed has been saved it should be sown at once and the boxes or seed-pans stood in a cold frame or cool greenhouse. Wherever possible choice Liliums should be raised from seed. Here I would warn cultivators who have little experience of raising Lilies from seed that some species form bulbs without showing any signs of germination, and seed-pans with tiny bulbs are often thrown away.

Macleania insignis is a very beautiful plant for the cool conservatory, and its long, slender shoots are well adapted for training over the sides of the greenhouse. Another point in its favour is the fact that it will succeed in a partly shaded situation. It flowers more or less all the year round, and the bright Vaccinium-like flowers and dark evergreen foliage are very attractive. It is easily propagated at any time by means of cuttings, and does best when planted out in a well drained bed of rough, lumpy peat and loam with plenty of coarse sand to keep the whole porous.
Royal Botanic Gardens, Kew. J. COURTS.

EDITOR'S TABLE

A FINE LILY.

Very rich in colouring, fine in shape, substantial and of good size was a bloom of *Lilium speciosum* which arrived recently from Mr. J. Henry Watson of Withington, Manchester. The spray was gathered from outdoors. Mr. Watson considers the variety, which has now flowered for the first time, being one of the offspring of a batch of seeds obtained several years ago from the Yokohama Nursery Company, an improvement on any known form of *L. speciosum*. We should very much have liked to compare it with a typical blossom of *L. s. magnificum*, but one was not to hand. It is very difficult to carry in one's mind's eye the minutiae of colour and form which would enable a satisfactory comparison to be made, but the flower sent was certainly admirable and of fine substance, colour, form and size. With the petals straightened out the flower measured about 7ins. across, the diameter of a very respectable Auratum Lily.

Correction.—Owing to a typographical error, the plant illustrated at the bottom of page 500 in our issue dated October 7 was inadvertently described as a *Berberis* instead of *Spirea* Thunbergii.

M. Corveon Honoured.—Alpine lovers and readers generally will be pleased to hear of the distinction conferred on our valued contributor M. Henry Corveon by the Jury of the International Horticultural Exhibition at Brussels. The Jury after closely inspecting more than twenty-five volumes from the pen of the distinguished author of "Fleurs des Champs et des Bois," asked permission to add to the Diploma of Honour which they awarded "the warmest congratulations of the Jury," unique distinction.

National Carnation and Picotee Society.—At a committee meeting of the above Society on the 30th ult. it was decided to hold two separate exhibitions of Border Carnations in 1923, the earlier one on July 8 and the later on the 23rd. This obviously will extend the chances of all classes of Carnation growers to stage their flowers at their best, and it is to be hoped that the opportunities will be accepted by growers who have not hitherto managed to bring their flowers up to Vincent Square.

The United Horticultural Benefit and Provident Society.—The annual festival dinner of the above Society was held at the Imperial Hotel, Russell Square, W.C.2., on October 4, Mr. Leonard Sutton presiding. Among the large number of guests was Sir Frederick Keeble. In his speech the chairman briefly outlined the history of the Society and explained to the visitors what good the Society was doing. The most interesting event of the evening was the presentation of a gentleman's wardrobe and barometer to Mr. C. H. Curtis in appreciation of his services as chairman of the committee for twenty-one years.

ANSWERS
TO CORRESPONDENTS

FLOWER GARDEN.

TREATMENT OF LILIUM AURATUM (M. C., Norfolk).—We suspect that the soil in the bed near the stream is too wet and cold during the winters for the well-being of the Lily bulbs, and in such a position it would probably be best to lift the bulbs during the late autumn. Unless it is intended to purchase fresh bulbs each year it would be best to grow the Lilliums in a more suitable place, and especial attention should be paid to shelter from rough winds. A light, rich soil is the most suitable, and the bulbs should be planted quite 6ins. deep.

CHRYSANTHEMUMS FOLIAGE UNHEALTHY (C., Chester).—There is some sign of thrips on the Chrysanthemums, but the main cause of the trouble appears to be overfeeding. Great care is needed with this variety (H. W. Thorp) in the application of manures.

HARDY PERENNIALS ("Sussex by the Sea").—The herbaceous perennials that would give a display with the least attention would include German Irises, perennial Sunflowers, Day Lilies, Michaelmas Daisies, Anemone japonica, Golden Rod, Helianthus, *Liatris pycnostachya*, *Lysimachia clethroides*, *Lythrum roseum superbum*, *Megacodon confidolus*, *Papaver orientale*, *Polygonum amplexicaule*, *Pyrola elagnosum*, *Rudbeckia californica*, *R. maxima*, *Spiraea palmata*, *Veronica latifolia*, *V. virginica* and the hardier early-flowering Chrysanthemums, such as the Masse family and *C. Normandii*.

LILIES UNSATISFACTORY ("Lily," Glasgow).—Our correspondent does not give the variety of Lily he has grown in a box for two years. Undoubtedly the cause of the stunted growth is exhaustion of nutriment in the soil and general weakening of the bulbs. After the first year the bulbs should be planted in the border in due course or thrown away and new bulbs planted in their place. The bulbs are, probably, very small now if examined. Use new compost and new bulbs.

GRASSES AND CLEMATISES ("Cotswold" and W. R. J.).—The Grass *Festuca Crinum-Ursi* belongs to the *Fescue* Grass genus, and these latter grow freely all over this country, forming some of our best pasture land. Hard *Fescue* will thrive in very poor soil, grows freely by the roadsides in the country, is very dwarf, seeds mature rapidly, and the reproduction of the plant is assured throughout the season. *Festuca Crinum-Ursi* was introduced in this country about the year 1890. It only grows 3ins. high, and will establish itself in any ordinary garden soil. It is considered ornamental, but not much is known about it generally as a garden plant beyond use on rockeries, where it succeeds. "Cotswold" should prune his Clematis as he would *C. montana*—thin out weakly shoots and decaying ends of older wood. If overcrowded, some of the big shoots may be shortened considerably. "W. R. J." would probably find "British Wild Flowers," by Lubbock, suitable. He should write to The Abbey Library, 1, Little College Street, Westminster, S.W.

PRIMULA CALYCYNA ("Bismarck").—There should be no special difficulty in flowering this old species if it is grown under fairly cool conditions. That is, it should not be exposed to the full sunshine in a small town rock garden. With most of the alpine species winter damp is their chief enemy, and to combat this the crowns should be kept fairly high and pieces of sandstone may be placed around them.

ROSE GARDEN.

ABOUT ROSES FOR GROWING (R. M., Botness).—Hugh Dickson, a strong-growing variety; Irish Elegance, vigorous in ordinary soil; Lady Pirrie, vigorous; General McArthur, strong growing; Golden Emblem, vigorous; Ophelia, moderately strong growing; Mrs. George Marriott, not as vigorous as the above named; and Mrs. David McKee, similar to last-named variety.

ROSES ATTACKED (T. H. S., Andover).—The Roses are attacked by the ordinary rose rust fungus (*Phragmidium subsectileum*). This fungus attacks also wild Roses, and may often spread from these to the cultivated ones. The fungus passes the winter on fallen Rose leaves. It is therefore important to collect and burn all these as far as possible so as to prevent the possibility of new infection in spring. The first stage appears in spring in the form of orange masses of spores on the shoots, and at this season, at the end of April or during May further infection may be prevented by spraying with a rose red solution of potassium permanganate, a spray that may also be used as soon as any fresh outbreak is seen.

TREES AND SHRUBS.

CALIFORNIAN BUSH POPPY (T. S. C.).—Our correspondent must not cut down the plant until winter is passed. The safest plan is to leave the plant untouched till new shoots can be seen growing near the base of the plant in the new year and then to cut back the stems to these shoots. If grown in a sheltered place and treated in the way described the plant will soon increase in size in the Southern Counties.

THE GREENHOUSE.

CARNATION RUST ("Shandon").—To prevent rust in Carnations maintain a dry atmosphere and ventilate freely.

CHRYSANTHEMUMS, CARNATIONS AND BULBS IN A VINERY (P. H. H. M., Longfield).—The period during which our correspondent proposes heating the vinery to keep out frost would be from November till March. Almost the whole of this time the Vines should be at rest, and until they are started—forced—again only frost must be excluded and not any temperature maintained unduly to excite growth of Vines. The flowers named do not require much heat, just sufficient to expel moisture and frosts. The paraffin stove will answer the purpose if the wick is trimmed daily, fresh oil put in and, after lighting, duly regulated so that the wick does not emit smoke. The Vines will not be injured.

FRUIT GARDEN.

PLUM COE'S GOLDEN DROP (G. C. D.).—If our correspondent has space in which to plant a Victoria, bush or pyramid in form, within 10ft. or so of the trees of Golden Drop, the setting of the fruits of the latter will be assisted considerably by bees and insects. Judging from the description given, we think that the condition of the

roots could be improved. To this end a surface mulch of 4 pecks of fibrous loam and 1 peck of lime applied in November to each tree would prove very beneficial.

GRAPES UNSATISFACTORY (A. L. L., Mon.).—The trouble with the Grapes does not arise from the attack of fungi or insects, but from something wrong in cultivation. Probably the ventilation has not been consistently well looked after, and the border may not be in good order—well drained and properly supplied with water.

APPLE ELLISON'S ORANGE (H. C. G.).—Ellison's Orange is similar to Cox's Orange in both form and colour, also in regard to flavour. The tree succeeds where Cox's often fails to grow satisfactorily, making strong shoots. The cropping qualities, too are good. It is in season a month earlier than Cox's, but keeps well in average seasons. It is, undoubtedly, an Apple of high merit, but we think that there is room for both—the variety in question and Cox's, as the latter always sells well.

PEARS DISEASED (M. G., Hinksey Hill).—The disease of the Pears is caused by a fungus, not by a caterpillar. The fungus is *Fusicladium pirinum*, and the best treatment is to cut out all the shoots and spurs showing cracks in the bark or signs of disease during the winter and to spray the trees with Bordeaux mixture just before the buds burst and again after the petals fall.

MISCELLANEOUS.

SOUTH AFRICAN FRUIT ("Gardener," Chingford).—From the description given it is not possible to name the fruit with any degree of certainty, and in the absence of the fruit the best we can do is to suggest that it may be the Loquat or Japan Medlar (*Eriobotrya japonica*), although this is not a native of South Africa. As no doubt our correspondent realises, the phonetic spelling of a native name is often of very little guide as a clue. As the seedling develops it should be an easy matter to ascertain whether or not our guess is correct. The Loquat makes a handsome wall shrub and will grow well in any garden that is not very heavy.

ERADICATING PLANTAINS AND DAISIES FROM LAWN (A. W., Derby).—The Wickham Weed Eradicator will be found a handy implement to use for destroying coarse weeds on lawns. It can be charged with any good liquid weed killer and, if the spike is pushed well down into the rootstock, Plantains soon die. They can then be removed and the hole filled either with a piece of fresh turf or fine soil and sown with a pinch of grass seed.

BOOKS DEALING WITH ROSES (A. G. H., Barrow-in-Furness).—The history of the present-day Rose is well treated in "Roses: Their History, Development and Cultivation," by the Rev. J. H. Pemberton, and published by Longmans and Co. This work also deals with pests and diseases, but the most up-to-date information on these matters is to be found in a publication of the National Rose Society, which is issued free to all members subscribing 10s. 6d. and upwards.

VARIOUS QUESTIONS ("Summer").—When the leaves begin to fade and the stems to mature the latter should be cut down to within 6ins. of the ground in the case of Hollyhocks. If left outside during the winter, surround the stems with ashes. Hydrangeas may be grown outside, remaining in the open all the year round in Surrey. All runners—forming now—on Violets should be cut off forthwith. The surface soil must be loosened occasionally between the plants and decaying leaves removed. Take strong cuttings of the Violas and insert in sandy soil in a cool border or rough frame. The old plants will deteriorate, so young ones must be raised annually.

NAMES OF PLANTS.—K. M., Birkenhead.—Pyrus Aria, "White Beam"; "Torquay"; 1, Rose Mrs. Wemyss Quinn; 2, Rose G. Nabonnand; "Dinner"; Physostegia virginiana, False Dragon's Head; R. H. B., Fife.—*Taenosa mixta*; E. W., Luton.—1, *Cotyledon glauca*; 2, *C. Scheideckeri*; 3, *Sempervivum tabularium*; 4, *Cotyledon clavifolia*; 5, *Fuchsia triphylla*; 6, probably *Veronica Ingrami*, specimen poor; 7, *Veronica Andersonii variegata*; 8, *Begonia fuchsoides*.

NAMES OF FRUIT.—(F. M. J.).—Apples; 1, very much like Cellini; 2, unnamed seedling. If trees are raised from pits, the fruits are certain to differ from any known Apple.—T. S. C.—Apple Cellini—"Nagrom"—Apples; 1, Lord Saffell; 2, Wenester Pearmain; 3, immature, please send later; 4, Old Hawthornden; 5, Beauty of Stoke; 6, Bramley's Seedling; 7, Margil; 8, Tower of Glamis; 9, cannot identify; 10, Waltham Abbey Seedling; 11, Carville Rouge Pincee, specimen immature; 12, Pott's Seedling; 13, Striped Bocking; 14, Cellini.—E. S. S.—Apples; 1, Blenheim Orange; 2, Emperor Alexander; 3, Lady Beniker; 4, Sandringham; 5, probably Pearmain's Pippin, specimen malformed; 6, Bramley's Seedling, poor specimen.

GEORGE ELSOM, Dept. F, SPALDING, LINGS.

DECORATIVE HARDY CRABS

WITH the possible exception of the Flowering Cherries, there is no group of flowering trees which is so valuable as that which embraces the various flowering and fruiting Crabs. The Crab Apple of our hedgerows, *Pyrus Malus*, is by no means destitute of beauty, but for the garden it has been quite surpassed by some of its varieties and hybrids. Of varieties the Red Astrachan Apple, P. M. var. *astracanica*, with a long, thin stalk and bloom-covered crimson fruits, and P. M. *pendula* (usually called Elise Rathke in gardens), handsome in flower and with yellow fruits, are probably the best, though many of the Cider Apples of commerce are well worth growing for their beauty of flower and fruit alone.

The true Siberian Crab, *Pyrus baccata*, is an exceedingly decorative tree, being handsome when in flower, but chiefly notable for the brilliant red globular fruits, the better part of an inch across and usually produced with the utmost prodigality.

Pyrus prunifolia, with more elongated fruits, which are crowned with the persistent calyx is, so *Bean* suggests, perhaps a hybrid between P. *Malus* and P. *baccata*; at any rate, its wild habitat is not known. Like the true Siberian Crab a somewhat variable plant, it is, as a rule, less effective than that species when in flower, but is very handsome when the fruits colour. There is a weeping variety (*pendula*), and several yellow fruited forms, most of which are quite pleasant eating. *Pyrus cerasifera* is a beautiful Crab: is said to be a cross between P. *prunifolia* and P. *baccata*. The fruits are purplish red and about the size of a Cherry and the tree is very handsome when in flower.

Pyrus Ringo is probably a hybrid, but was introduced to English gardens from Japan. This is quite the handsomest of the yellow-fruited Crabs and among the most conspicuous of yellow-fruited shrubs and trees. The flowers are blush when fully expanded, but the rosy buds are very effective.

Pyrus Scheideckeri is another of, doubtless, hybrid origin. It is alike remarkable for the profusion of its blossom and the vigour of its growth. The flowers are soft rose in colour and

the fruits, which are not usually produced very abundantly, are yellow. Closely allied to this is P. *floribunda*; indeed many authorities think that P. *Scheideckeri* has *floribunda* "blood." When in bud, or before many of the flowers are fully expanded, this is a very beautiful (and well known) tree. The expanded flowers are pale pink, fading off almost to white, but the unexpanded buds are a beautiful clear rosy red. The variety *atrosanguinea* is an improvement on the type, being richer in colouring though even here it is the bud colour which chiefly counts. The yellow

fruits are scantily produced and are scarcely ornamental.

With purplish rose flowers, red-purple fruits and purplish wood, *Pyrus Niedzwetzkyana* might well be called the Purple Crab. It appears to bear a similar relationship to the Crab Apple of our hedgerows to that borne to the Filbert (*Corylus maxima*) by the Purple Filbert—var. *purpurea*. However that may be, P. *Niedzwetzkyana* is a sufficiently beautiful tree, though one would hesitate to include it in a short list of ornamental flowering trees. *Pyrus Eleyi*, the flower of which was figured in THE GARDEN for May 25 last, page 240, is said to have been raised by crossing this species with P. *floribunda*. Its foliage and fruits have something of the purplish hue of P. *Niedzwetzkyana*, but it is much freer both in flower and fruit. The fruits are much smaller than in the purple parent, indeed they would easily pass muster as those of some variety of the Siberian Crab. *Pyrus Eleyi* seems destined to take its place as one of the indispensables of this valuable family.

Pyrus angustifolia is a quite interesting species not so often seen in gardens as it well might be. The flowers, which are very protusely borne, are pale pink fading almost to white. The double form more often seen in cultivation as P. *angustifolia flore pleno* is, according to *Bean*, really a double form of the closely allied P. *ioensis*, which is distinguished by its persistently woolly foliage.

Closely allied to these two species is P. *coronaria*—the American Crab—which comes from the eastern states of North America. The whitish flowers are freely produced and exceedingly fragrant—the scent is said to resemble that of Violets, but that is a matter of opinion. It is later flowering than most species, the blossom lasting usually well into June and additionally valuable on that account. The comparatively large fruits are greenish yellow and of little merit from any point of view. This is, for a Crab Apple, a large-growing species and a very valuable one, though not commonly seen in gardens.

The well named *Pyrus crataegifolia* is a shrub or small tree, very uncommon at present in this country. It blossoms in June when the pure white flowers are

THE PURPLISH CRIMSON FRUITS OF PYRUS ELEYI.

EARLIEST OF FLOWERING CRABS, PYRUS SCHEIDECKERI.

AN EFFECTIVE GROUPING OF PYRUS FLORIBUNDA.

exceedingly effective. The reddish fruits are not particularly attractive, being not unlike those of *P. floribunda*, but the foliage usually colours beautifully in autumn. This is one of the finest flowering shrubs for a small garden it is possible to imagine but, unfortunately, not easy to procure.

Pyrus Parkmanni, or to give it its proper name, *P. Halliana*, unlike the last mentioned is exceedingly common in gardens and nurseries but, in the writer's opinion, it is too largely planted. Somewhat in the way of *Pyrus floribunda*, but with flowers usually semi-double, it is more erect in habit and less free flowering than that admirable tree. It seems rather larger habited than *floribunda*.

The Oregon Crab, *P. rivularis*, is often listed by Continental nurserymen. It is an American species of no particular beauty or value. *Pyrus Toringo*, to which it is closely allied, has rosy flowers and resembles in many ways *P. floribunda* from which, however, it is readily distinguished by the very small (pea sized) fruits. The more recently introduced *P. Zumi*, with larger fruits bright red in colour, may perhaps prove a valuable garden tree. The flowers are pale pink. *P. Sargentii*, more recently introduced still, forms a low shrub—not more than 3ft. or so high—smothered in spring with pure white flowers, followed by globular fruits which are bright red when ripe.

Pyrus spectabilis is one of the most worthy of Crabs grown for beauty of flower, but the yellowish fruits are not attractive. This species grows into a tree of some size, much larger than *P. floribunda* for instance, which species it resembles as regards flower colour, though the individual flowers are larger. There is a semi-double variety—*flore pleno*—which perhaps retains its colour a little better, but the typical form is, as Crab Apples go, particularly long-lasting in flower.

The Sikkim Crab, *Pyrus sikkimensis*, is rarely seen in Britain outside botanic gardens. It forms an admirable small tree, valuable both for its abundant white blossom and rather pear-shaped dark red fruits which, in the quantity it produces them, are exceedingly showy. Undoubtedly closely allied to the true Siberian Crab, it is quite distinct as a garden tree and indeed much more refined.

There are several hybrid fruiting Crabs of great value for garden decoration of which the origin is uncertain and which can hardly be referred to any one species. One of the best of these is *Transparent*, of which the fruits when quite ripe become more or less translucent. Their colour is yellow with a bright red flush on the sunny side. John Downie, with apple-like fruits sometimes 2ins. across, is perhaps the finest of all both as regards flavour and appearance. The tree is, naturally, handsomest when roped with fruits, but the individual fruits are then considerably smaller. The colouring is a bright, if pale, orange with a scarlet cheek. Other unclassified varieties include *Dartmouth*, with crimson fruits covered with purplish bloom; *Fairy*, yellow and crimson; *Orange*, clear soft yellow; and *Transendent*, yellow and rosy-red.

The fruits of almost all these Crabs have an economic value for jelly making, but most of them are mainly grown as ornamental trees and shrubs. They are not particular as to soil so long as their root-run is sweet and not too poor. Taking them for all in all, they succeed best on rather lighter loams than those which would be considered ideal for an Apple orchard, but any soil not deficient in lime will, if thoroughly cultivated, suit them quite well.

Many people think it a pity that the Apple family, previously considered a separate genus—*Malus*—should now be combined with the totally dissimilar White Beams, Service Trees and Rowans, the Pears and a couple of smaller, less known groups, to form the huge genus *Pyrus*. It is certainly very confusing to the average amateur gardener.

MICHAELMAS DAISIES

No longer garden Cinderellas, thanks to "Ballard, Beckett and Co."—Cinderellas do not look well overdressed—Notes on Beauties at the Autumn Shows—About "withering."

MICHAELMAS DAISIES are slowly but surely worming their way into the autumn garden. The triumvirate of Sunflower, Dahlia and Chrysanthemum no longer has it all its own way. At last—advisedly I say *at last*—this stranger from North America has found some good friends like Mr. Beckett and Mr. Ballard, who have waved their wands of selection and hybridisation over its ancient colourings and habits, with the result that it can no longer be denied an honoured place in the autumn Paradise of the Wise. There have been writers who have doubted the appropriateness of the surname for a family whose flowering extends from soon after Lammas right on to Martinmas; just as I would question the appropriateness of the suggested alternative, Starwort, for except in acris I can see no particular resemblance in their shapes, sizes and colours to the stars of heaven beyond that of an endless number of other flowers. But if I must discuss names, I would like some time or other to go into the history of Novæ-Angliæ and Novi-Belgii and find out why—if it was not pure chance—these branches of the family were so christened. Anything that concerns what I think I may without hesitation call its most important garden section must be of interest. One had only to look at the beautiful exhibits of Mr. Ernest Ballard, Mr. H. J. Jones of Lewisham, Mr. Amos Perry and Mr. Wells at the R. H. S. Autumn Show to see how the Novi-Belgii section eclipses all others. These others, though, are also very lovely, and have many devoted admirers.

The award of merit given on the same occasion to a Novæ-Angliæ—Barr's Pink—was a gentle reminder that it is so. Barr and Sons were among the first to give a prominent place in their herbaceous catalogue to Michaelmas Daisies, which is the soulless trade equivalent to an individual's tender place in his heart. I was glad to see they are still on the *qui vive* for good things. What a contrast this vase was to that of Little Boy Blue from Mr. Ballard, a new and low-growing variety with enough deep purple-blue ray florets to make it a so-called double. It, too, received an award. It is one of the popular Novi-Belgii section, which I cannot help sighing over, as the "advances" which are being made are too iconoclastic by far to please me. A multitude of petals (?) and horrible distorted centres are ill exchanges for the quite-all-right ray florets and the smart, well defined centres of Attraction

and Climax. I fear, however, we gardening folk are a somewhat novelty-ridden crowd, and that anything that is new is apt to appeal to us in a way that is often out of all proportion to its intrinsic merits. This is why some of the good old stagers drop out.

I have had the very great pleasure this year of seeing two exhibits of Mr. Ernest Ballard's in London. One on September 19 at the R.H.S. Hall and the other at the big Autumn Show on October 3. What, however, pleased me more than seeing the flowers was seeing the man

THE NEW ASTER, "CORDI-BELGII" PIONEER.

himself; and again what pleased even better still was hearing what he said about distorted centres and doubles; and lastly, and best of all, to find that he is bent on seeing it new and probably untried crosses will not give us something quite out of the ordinary. I saw a vase of a delightful pink graceful variety tucked away behind others in his R.H.S. Hall exhibit. It is well named Pioneer, for it is the result of a cross between cordifolius and a Novi-Belgii. Mr. Ballard thinks he has broken entirely new ground. Whether he has or no, he has given us something very nice, something that reminds me of that exquisite variety which seems also to have cordifolius blood in its veins and which is named after Mr. Ballard's rival, Edwin Beckett. I happen to have two Becketts in my collection, both good, as of course any Michaelmas Daisy bearing such a name should be, but one quite out of the ordinary in

its light, graceful habit and delicately poised flowers of the very palest lavender. Mr. Ballard's group at the Holland Park Rink was one of the features of the Show. It was not very large, but all the flowers were fresh-looking and good. All the varieties, or very nearly all, were his own raising, and among the very best "looking fine" were the semi-single pale mauve Queen of Colwall and the deep red-purple Purple Emperor with its rather spidery-looking petals. Frankly, I was disappointed with the quantity of Michaelmas Daisies at the Show. I expected to find far more than there were. I knew, for example, that Mr. H. J. Jones of Lewisham intended to "lick creation" in the group he would put up. When I asked him why he had not done so, he laconically replied, "The weather." Nevertheless, there were a number of fine varieties scattered here and there in the different groups. Among those which appealed to me were the following: Rycroft Pink, a good example of a rose Novæ-Angliæ; Kate Bloomfield (raised by Mr. F. G. Wood), another Novæ-Angliæ with somewhat small blooms of an exceptionally clear and bright rose, several shades brighter than Barr's Pink and, I thought, more attractive in a bunch; Rev. Charles Lunn, also in Mr. F. G. Wood's group, a beautiful soft blue-purple Novi-Belgii; Cattleya, a semi-double of a very attractive shade of mauvy pink, a variety which I find I noted when I visited Mr. H. J. Jones at his garden at Flower House, Lewisham, and which is certainly one of the most popular ones in my own collection at Whitewell; Harold Reuthe (raised by Mr. Reuthe), one of the best rose pinks that I have seen, with its flowers arranged after the fashion of the beautiful Louvam; Sam Banham, one of the best whites, but I feel it is rather a libel on Climax to describe it as a snow white edition of what I am very much disposed to think is the best Aster ever raised; General Léman, a most attractive rose with considerably less blue in it than there is in the rose of Mons (this last named was everywhere, whereas I only noted one solitary vase of the brighter and better General; Mrs. Bowman, noteworthy on account of its orange centre and deep purple ray florets or, as one so often for convenience calls them, petals; Grey Lady, for those who like such spidery-petalled forms as Miss Eisle, a gem with its pale soft pink tinted lavender flowers; Advance, a good example of an Amellus (if we may include the section under Michaelmas Daisies) of the colour of the well known King George; and Rapture, a good pink.

Before I close I want to draw attention to a strange withering of the foliage, which seemingly may take place at any period of a plant's growth and which picks and chooses its plants without any visible rhyme or reason, as the victims are necessarily never all together. I am told that Wisley has said that it is no disease, and this view of the matter is supported by what we find in the "Garden Doctor," by Mr. Chittenden, who is the head of the R.H.S. Gardens at Wisley. Under the head of Aster the only ill noted to which the family is heir is the beastly fungus Erysiphe cichoracearum (mildew). Disease or no disease, one wants to avoid it if possible. Can any readers who have experienced it throw any light upon its cause or cure? It has never appeared here until this year, when I bought a number of plants from four different sources to make up my collection, which now numbers about 125 varieties. Mildew I have known in previous years, but it has never been so bad as in the present. There was no sign of it until a spell of cold, windy and wet weather came in the early part of September. By timely spraying with a mildew wash it has been kept in check, but here and there are plants on which it has had

no effect. It is doubtless the result of their different constitutional susceptibilities. This is a curious fact. The Michaelmas Daisies are grown in three different parts of the garden. In two the

plants have been "well done," in the third they have been half starved—at least that is what they look like—and the rooting medium is on the dry side. Here there is not a speck of mildew. Is

it misplaced kindness to do Michaelmas Daisies very well? When one's plants go wrong it is small consolation to think one lives in the spraying age of gardening.
JOSEPH JACOB.

ROUND ABOUT A WOODLAND GARDEN.

THERE is no more delightful season in a woodland garden than those few weeks which come between the autumnal equinox and the leaf-fall of the Oaks. It is not only a season in which one may enjoy the colour splendours of waning foliage and ripening fruit, but one in which Nature, claiming a brief indulgence in her ancient prerogative of untidiness, demands to be left alone. At any rate, if there is any of that inherent laziness in the gardener, which is the common heritage of man, it is during the good month of corn and wine and oil that he is most liable to be affected by it. So we gladly (when we may) accede to Nature's mandate, roll up our blue aprons, and listen to the Broom pods snapping in the sun. It is possible in such a moment to watch the brown leaf sink softly as a curled feather in the still air without rushing for a besom, to hear a tiny rustle in the herbage of the bank without thinking of a mouse trap, for it is Nature's armistice and ours. If we have no blue apron to roll up, we can always grow one of those beards which a considerable section of the daily Press seemed to think were not the least entertaining of the exhibits at the Holland Park Show the other day.

It so happens that a dry, sunny spell having set in after the drenching of the later summer, there are more flowers in our October garden than is usual at this season. The Heaths have carried on exceptionally well, and among those which are of special merit just now the Dorset Heath, *Erica ciliaris*, must take a foremost place. The very large clear rose purple bells and the soft, grey-green of the elegant foliage combine to give an irresistibly charming effect. *E. Stuartii*, a hybrid discovered in Ireland, with small white bells distinctly tipped with vivid carmine, is even better than it was a month ago. *E. stricta*, naturally a late bloomer, is of course at its best and always distinctive. While most of the *E. vulgaris* (Calluna) clan rigidly adhere to their proper season, the dark-foliaged, deep crimson *Alporti* will usually give some colour throughout the autumn; and another form which is always later in coming into flower than the rest of its class and which is now a mass of colour is *E. v. var. aurea*. Though not a choice species, *E. scoparia* is useful for late autumn flowering, and in passing I may mention that there is a dwarf and prostrate form of this Heath which, as a close-set foliage plant of a peculiarly striking moss green, suggests possibilities in woodland plantings. I saw this recently at Kew and made a note of it.

Lyranthus empetriformis can generally be relied upon to flower at the "back-end," and it

is now bearing a good crop of blossom; but perhaps the most attractive of all the peat-loving plants in bloom is *Polygala Chamabuxus*. This grows and spreads in large, dense mats, and would always flower abundantly in our woodland loam were the mice less fond of its blossom buds. But it so

common shrub, not very effective in flower, but excellent in leaf colour is *Ribes aureum*. There are some first-rate varieties of this Currant, but a well grown bush of the type is not to be despised when every leaf is stained a brilliant vinous crimson for, perhaps, six weeks or more.

Few autumn flowers can be grouped with such pleasing results in open woodland as *Montbretias*. Their range of colouring is now so wide that one may select almost any shade from pale yellow to deepest orange or bronzy vermilion, and they will always be in harmony with their surroundings. Groups set in creeping Ivy or other herbage have been established here for years, and though the flowers would doubtless be finer and more plentiful under more orthodox treatment, they could hardly fulfil their purpose better. Enough is sometimes better than a feast in this matter. So much might also be said of *Antholyza*. I can raise no enthusiasm for "Aunt Eliza" as an individual, but "distance lends enchantment," and the October sun and a woodland setting does the rest. Both *Montbretia* and *Antholyza* are worthy successors to the *Alströmerias* in this woodland planting, the last in the sunniest places. The Kafir Lily, which, like *Montbretia*, is apt to demand too much space and attention when in the border, is also admirable in such situations. It does best perhaps in grass, and very seldom needs

PURPLE FRUITS AND RED-PURPLE FOLIAGE OF *VITIS VINIFERA PURPUREA*.

happens that this year one patch has been left untouched, with the result that the low mound of myrtle green leaves is bristling with pea-shaped flowers in the rose purple and yellow of the variety *purpurea* and the ivory and yellow "butterflies" of the type. The even more delightful P. C. var. *Vayrede* planted two years ago is, however, still nursing a grudge. But one must be patient with these things.

The very keen yellow of the tall, upright *Genista tinctoria* against the fiery hues of an Azalea bank seem to strike a somewhat harsh note at this season. Individually the plant is attractive and welcome enough, but its shrill charlock yellow suggests spring rather than autumn. *Spartium junceum*, still as full of flower as ever, just escapes the sulphur tint, but even it is better away from the mellow hues of autumn foliage plants. Mention of Azalea reminds me that someone in a recent issue of *THE GARDEN* regretted the disappearance from our gardens of the old yellow Honeysuckle Azalea (*A. pontica*), but I am happy to feel that we still have a quantity of this true and easily grown old shrub. In range and splendour of leaf-colouring *A. pontica* has few rivals. The best (selected) forms are admirable in colour and size of blossom, and the species is well worth growing for its fragrance alone. Another

any attention if one is not too exacting as regards quantity and size of flower-spikes.

A bush of *Abelia chinensis* in full flower at this season is a cheerful object, and if it does look rather spring-like and bridal in its apple blossom pinky white there is enough bronze and ruddy crimson about it to harmonise with the prevailing tints of the hour. So, too, with *Papaver rnpitragum*, whose delicate green leaves seem to belong to any other season than this; but when this handsome Poppy, which seeds freely in sun or half-shade, opens its large apricot blossoms nothing could be more in sympathy with its surroundings, and never does it look quite so handsome as it does to-day. Under some Hollies, now laden with berries changing to orange, and about the roots of old Oaks hardy *Cyclamens* of various kinds give gay patches of rose pink; while along the waterside, *Omphalodes cappadocica* and *O. nitida* are making worthy efforts to equal the spring display of their incomparable blue. Some forms of *Gentiana asclepiadea* in dark blue, light blue and pure white, with arching stems from 18 ins. to 3 ft. in length are also here, nor can one overlook the gorgeous colour afforded by the autumn foliage of *Paeonia albiflora grandiflora*, which for nearly two months has gradually changed from a uniform beetroot purple glossed with bronze

to rich crimson and so on to scarlet. But even this splendid thing cannot excel the glory of that excellent little Vine, *Vitis vinifera purpurea*, which is here so planted that it will be between us and the evening sun. In such a position the plum-coloured foliage will be lit with a blood crimson of amazing depth and brilliance, an effect which can otherwise never be enjoyed.

Anemone japonica is always a reliable stand-by in the autumn border, but not all of its kind are really satisfactory for the wild garden. Some are too weak in the legs, some seem too cold for association with the glowing splendours of the hour. *A. j. crispifolia* (Lady Gilmour), with curiously crimped leaves and single, wine-stained flowers, is one of the most satisfying here, and a good word must be said for an old rift, semi-double variety in crimson-purple, a very pest in the wrong place, but admirable in the right one. "Grassy" plants, a broad and loose term

embracing everything from the big Bamboos downwards, are seldom so attractive as they are in the autumn garden, for there is a whispering softness about them that just seems to fit the mood of the moment when the little gossamer spiders are teaching us that to them at any rate "gliding" is no novelty. What, for example, can be more in sympathy with the spirit and colour of the woodland than a broad clump of *Apera arundinacea* whose countless blades of ruddy gold are veiled with the graciously curved seed-bearing panicles all shimmering with crimson and bronze and iridescent light? It is the last word in elegance, refinement and harmony, just as the hot torches of the *Kniphofias* are the last and fiercest word in the glow of autumn's embers. The ill-at-ease man may calm his fretful soul by a gentle contemplation of the one, he may warm his hands at the other, and thank the god of gardens for both.

A. T. J.

FRUIT TREES FOR ORNAMENT

Properly used, Apple, Pear, Plum and Cherry will serve to help the garden picture.

THE use of fruit trees in the garden calls for a certain amount of imagination if their full decorative value is to be utilised in the garden scheme. On the one hand, most fruit trees are exceedingly beautiful when in blossom and again when in fruit, while some, notably Pears and Cherries, are valuable for their autumn colour; on the other, with some exceptions, they are the reverse of decorative for a great part of the year.

Such trees as the Almond, the Sweet Chestnut, the Mulberry, the Blackthorn, the Cherry Plum and its purple variety (*P. cerasifera* Pissardi,) the Pomegranate, the Loquat, many sorts of coloured Crabs and, perhaps, the Walnut are principally grown in this country as ornamental trees. Some excel in beauty of bark, growth and foliage, some of flower, while with some the fruit

itself is the main attraction. Among shrubby fruits the Japanese Wineberry, *Rubus phoenicolasius*, and the Parsley-leaved Blackberry, *R. laciniatus*, are also largely utilised for their decorative effect. The purple-leaved Filbert, *Corylus maxima atropurpurea*, is largely cultivated for the sake of its appearance, but the green Filberts, many of which crop so heavily, are very effective when planted to form an alley roof, or raft, wide. They are really beautiful when bare of foliage, their wonderful twiggy being seen to greatest advantage when outlined in hoar-frost on a winter's morning. The summer shade they afford seems exactly to suit such shade-loving bulbous plants as *Erythronium*, *Cyclamen* and *Narcissus moschatus*.

The value and disposition of the various Crab Apples provides matter for a separate article,

and the use of the other ornamental trees mentioned is sufficiently understood, except, indeed, that it may be well to set down that the Purple Plum is much more effective when grouped than a commonly seen dotted here and there in single specimens. The Wineberry is emphatically a specimen plant, as when several are planted together one loses the grace of the elegantly arching golden-spined young canes. The Parsley-leaved Blackberry is commonly used for training on pergola or trellis. It answers for either purpose, but shows to best advantage when allowed to mound itself over shrubs of lesser worth in shrubbery or wild garden.

The main object of these notes, however, is to consider the use which may properly be made of the more humdrum fruits which no garden worthy of the name should be without—Apples, Pears, Plums and Cherries. Raspberries, Gooseberries, Black Currants and Strawberries are hopeless from a decorative point of view, so of them there is nothing to write. Red and White Currants and Peaches have some decorative value mainly on walls.

The standard Apple is a beautiful tree, especially when mature, and in small gardens it might well be employed in the parts of the garden which are, as a rule, entirely devoted to purely ornamental trees, shrubs and plants. That in such a position it is more difficult to keep the trees clear from insect and fungoid pests is usually considered axiomatic, but in actual fact such trees are often much cleaner than those grown together in an orchard, especially if the latter are somewhat neglected, which in private gardens—at least when judged by the standard of the commercial fruit-grower—they are apt to be. Still the arrangement is only suggested for gardens where space is very limited and in which no separate quarters can be devoted to hardy fruits.

From a practical standpoint the culture of Apples on pyramid or bush trees is to be commended. Where it is desired to use this fruit to help the effect of the general garden scheme, it is wiser to rely on standards, cordons and espaliers. Magnificent pyramids such as are to be seen at Gravetye certainly have a real decorative value, but there are few to-day prepared to devote the labour necessary to produce trees such as these. The grass orchard planted with standard trees is one of the most picturesque features of the countryside, and one that, with forethought, can almost always be used advantageously in the garden scheme. The lines of trees should run approximately north and south to allow the greatest possible amount of sunlight to reach the buds. Cross vistas from east to west are, however, easily arranged for, and he must indeed be an ignoramus at garden planning who cannot arrange avenues of fruit trees to define in part some of his vistas.

The grass orchard provides an admirable site for naturalising bulbs, particularly *Narcissus*, in turf, while around the trees where the soil should be kept turf and weed free, *Primroses*, preferably the wild one, and *Winter Aconites* will flourish. The writer well remembers a crop of Shirley Poppies around the butts of the trees in a fairly young orchard. The ashes from a garden bonfire had been spread upon this orchard. Evidently Poppy seed from plants thrown upon the heap for destruction had, being heavy, fallen through into the ashes and, strangely enough, escaped destruction. These self-sown Poppies—could one call them that?—were the finest the writer has ever had the good fortune to behold, and they looked singularly well placed there. Vistas which finish in "thin air" are never satisfactory unless defined by trees of such size as to form a natural cathedral. Some solid, preferably evergreen planting should be arranged to close

STANDARD CHERRIES IN BLOSSOM.

them, and in some situations room for this planting will have to be provided when laying out the orchard.

Pear trees of vigorous habit, such as the Catillac or Pitnaston Duchess, are so handsome all the year round, but especially when in flower and again before the fall of the leaf, that they should always be placed where they readily come under notice. Either might well be used as screen trees, for their rapidity of growth is very considerable. All Pears which are suitable for orchard culture are handsome, and they provide considerable variety of habit. Some of those the writer has tried successfully as standard trees on a fairly light and warm soil are, in addition to those

already mentioned, Williams's Bou Chretien, Jargonelle, Beurre Diez, Petite Marguerite, Conference and Durondeau.

Cordon and espalier Pears and Apples are of great value for a number of purposes. They might well be used to far greater extent than they are at present to cover the walls of buildings. To utilise such walls for the growth of choice shrubs which would not in our climate succeed elsewhere is understandable and praiseworthy, but to smother them wholesale with such common climbers as Irish Ivy and Virginia Creeper is worse than waste of valuable room.

Espalier trees (or cordons if preferred) form a very suitable backing for the flower borders

which nowadays often bound the principal paths in the kitchen garden. Cordon trees may be utilised to form a very handsome fruit pergola, though the fruit pergola need not be confined to such. Loganberries, Blackberries, Red and White Currants, even Gooseberries, may be pressed into service, and be at once useful and ornamental. The decorative value of Cherries, whether on orchard standards or on trained trees, needs no emphasising, but their special worth for planting on north walls cannot too often be reiterated. This fitness for a wall with a cold exposure is not confined to the Morello; it applies to the generality of eating Cherries. Red Currants, too, answer in such a position.

MIXED "FARE" AT VINCENT SQUARE

FOLLOWING so closely upon the great Autumn Show at the Holland Park Hall, many visitors were agreeably surprised to find so fine a display at Vincent Square on October 17. The hall was well filled with a great variety of interesting exhibits, chiefly of hardy flowers, though there were several interesting collections of fruit. Messrs. G. G. Whitelegg and Co. had some dishes of splendid Apples and Pears. The former included such valuable sorts as Cox's Orange Pippin, Allington Pippin, King of the Pippins, Royal Snow, Ben's Red, Peasgood's Nonsuch and Branley's Seedling, all admirable in size and colouring. Among the Pears there were dishes of Doyenne du Comice, Pitnaston Duchess and Beurre Clargéau. Boxes

of Apples as sent to market and of splendid appearance were shown by Mr. G. Trinder, Guildford Fruit Farm, while Messrs. Laxton Brothers had Laxton's Superb and Lord Lambourne, their two new Apples, whose appearance is a strong recommendation. Golden Hornet, a prolific, perpetual bearing, large golden Raspberry, shown by Mr. G. Trinder, attracted a deal of attention. It received an award of merit last year. According to the official list of awards posted in the vestibule, Lady Margaret Bickersteth, Cottingham House, Yorks, was awarded a card of cultural commendation for Sultan's Grapes, but search and enquiry failed to discover them.

Chief among the flowers were Chrysanthemums, and for these, associated with Sunflowers and

Michaelmas Daisies, in an imposing group Mr. H. J. Jones received his fifth R.H.S. gold medal of the year. Among the Chrysanthemums Red Almirante was of dazzling colour, even brighter than Verona. October Glow is a bright orange-scarlet variety that went well with Harvester. Another showy variety was Ethel Blades with deep crimson sprays, in the collection of Messrs. W. Wells and Co. This with the yellow Mrs. A. Thomson and Goucher's Crimson appeared to have been cut from the open ground. Their large Japanese blooms of Viscount Chinda (the new golden yellow), James Stredwick and the rich crimson Mrs. G. Monro were splendid. Those who prefer disbudded sprays found plenty to choose from in a large display by Messrs. K.

THE APTLY NAMED CARNATION TANGERINE.

ALMOST SCARLET FRUITS OF ROSA FARGESII.

Luxford and Co., who had such sorts as Countess (white), Goldfinch, Bouquet Rose, Nathalie (a single of rose terra-cotta colouring) and Mrs. M. Field (which is a deeper-coloured Normandic). Mr. Yandall of Maidenhead had a very bright and attractive group, Lichfield Purple, which was well shewn in this collection, is a beautiful shade of this somewhat uncommon colour in Chrysanthemums.

There was the usual quota of Orchids, and greenhouse plants were chiefly represented by Carnations and Sutton's graceful Lloydii type of Begonia. This latter is a very elegant, free-flowering strain which produces plenty of double and semi-double, pendulous flowers in a variety of colours. The plants are quite easily raised from seed and do well in a cool greenhouse. There did not seem to be any new varieties among the collections of Carnations. Messrs. Stuart Low and Co. shew their large White Pearl regularly and in quantity, which points to its being a free-flowering variety. The Allwoodii, too, seem to be as free-flowering and attractive in autumn as at midsummer.

Roses are becoming a trifle smaller, but, except for this, one might have imagined it to be August rather than October when inspecting such collections as those arranged by Mr. Elisha J. Hicks, Mr. G. Prince, Messrs. D. Prior and Son and the Rev. J. H. Pemberton, for all the blooms were beautifully fresh and of good colour.

It is only in a few places that frosts have checked the flowering of the Dahlias, so there were quite good displays by such growers as Mr. J. T. West, Messrs. J. Cheal and Sons and Mr. C. Turner. As at the Holland Park Hall Show, it was the small Paony-flowered sorts that were the most attractive. Winter Sun, Sweetness, Olive and Our Annie are excellent examples.

General border flowers included some very good Delphiniums, Lupins and Kniphofias in a large collection by Messrs. John Waterer, Sons and Crisp. Just inside the door the tall, snowy white plumes of Pampas Grass in the group by Mr. F. G. Wood immediately attracted attention and drew the eye to the bold plumes of the purple-tinted species Cortaderia Kermesiana, which is also very attractive as a large clump near the Temperate House at Kew. Messrs. B. Ladhams continue to stage their tall Lobelia hybrids in great variety. Of the bright-coloured sorts Queen Victoria, B. Ladhams and magnificans were perhaps the best, while the pink variety Mrs. Humbert is attractive. They all produce flowering stems quite 3ft. high, and have a long flowering period.

Vivid autumn colour was provided by the branches of Quercus rubra and Pyrus discolor in a collection by Messrs. J. Cheal and Sons. They also had a little group of New Zealand shrubs, including graceful Pittosporums and the deep blue shrubby Veronica Autumn Glory. Messrs. Skelton and Kirby had vivid sprays of Berberis Thunbergii and Crataegus Crus-galli.

Messrs. Barr's Nerines attracted the attention of lovers of graceful greenhouse bulbs. The cut spikes of the beautiful pink varieties, Jupiter and Miss Jekyll, with the glowing scarlets and crimson of Scintilla, Carolus and Vivid were especially good. Opinion seemed divided concerning the large plants of the hybrids Aurora and Hero, which bore exceptionally stout spikes of pink flowers. They were so tall as to give almost the impression that they were pink Agapanthus.

NEW AND RARE PLANTS.

Acer griseum.—This delightful Maple was introduced from Central China in 1901 by Mr. L. H. Wilson when he was travelling for Messrs.

James Veitch and Sons, and he says that mature trees have a very striking appearance when the peeling bark hangs down in large flakes, disclosing the fresh orange-coloured skin beneath. The tree from which the branch on view was cut is 18ft. high and has not yet reached that condition, but it is exceedingly beautiful by reason of the glorious intense crimson colour of the small, toothed, trifoliate leaves, which are borne in pairs on downy stalks. This fine down is also present on the undersides of the leaves, and there

BRILLIANTLY COLOURED FOLIAGE AND KEYS OF ACER GRISEUM.

is a denser brown tomentum on the seed keys. It becomes a deciduous tree up to 40ft. in height, and when better known will be greatly valued for its autumnal colour. Award of merit to Mr. C. J. Lucas.

Carnation Tangerine.—This is a very distinct Perpetual-flowering variety. The deep yellow ground and rosy stripes give the general appearance of rich salmon buff. It is a well formed flower, but there is no perfume. Award of merit to Messrs. Keith Luxford and Co.

Chrysanthemum Viscount Chinda.—A rich golden yellow Japanese variety of first exhibition size. The broad, drooping florets have an incurving tendency, and there is plenty of substance in them, so the blooms should continue fresh for a long time. First-class certificate of the National Chrysanthemum Society to Messrs. W. Wells and Co.

Chrysanthemum Godfrey's Triumph.—This name was given to an exhibition Japanese variety of rich colouring about a quarter of a century ago. For a long time it was very popular, but in the fulness of time was superseded by other sorts, though none had quite the same colouring. Now the name has been revived for a large, many-petalled single variety. The blooms have several rows of stout petals, which are slightly rolled at the edges and incurve at the tips. Award of merit to Messrs. J. Godfrey and Son.

Euonymus europæus Aldenhamensis.—This Spindle Tree differs from the type in being exceptionally fruitful and, perhaps, in the fleshy seed covering (the aril) being a trifle brighter. The branch of the type bought by the exhibitor for comparison was a wretched staving—a travesty of one of our most beautiful autumn trees. The

variety under notice is well worth growing on account of its exceptional freedom in fruiting. Award of merit to the Hon. Vicary Gibbs.

Gladiolus Oakfield.—A very handsome spike was shewn of this Priminius seedling, which approximates to the large hybrids. The well disposed blooms are not hooded, but have somewhat reflexed margins. It is of delightful warm rose pink colour, and the lower segments are spotted with the same colour on a pale yellow ground. We understand that this variety was raised from

seed sown early this year, and that the plant was of branching habit and fully 4ft. high. Shewn by Messrs. Lowe and Gibson.

Rosa Fargesii.—This is one of the most beautiful species in the autumn, when the long, bottle-shaped fruits have their rich crimson colour. The hips are lightly furnished with stoutish, dark spines. Among the extensive collection of Rose species near the Pagoda at Kew this species stands out, at present, as the most decorative of them all. Award of merit to Mr. J. C. Allgrove.

Brasso-Cattleya J. G. Macdonald, Langley Variety.—The reason for the tag on to the name of this gorgeous Orchid is not apparent and renders it very clumsy. However, it is a most beautiful bloom of large size and rich mauve colour, deeper on the lip, which is marked with orange. Award of merit to Messrs. Flory and Black.

Lælio-Cattleya St. George Variety Victory.—Another charming Orchid with a cumbersome name. The sepals of the very large flowers are of very pale, sparkling mauve colour, while, in almost startling contrast, the large lip is of rich velvety crimson shade. Award of merit to Messrs. Stuart Low and Co.

Miltonia spectabilis extraria.—For a time the Committee doubted the correctness of the generic title, but finally agreed that it was a Miltonia. The delicate, pale ivory white sepals are somewhat reflexed, and there is rosy purple marking on the lip. A most uncommon Miltonia. Award of merit to Messrs. Sander and Co.

Odontoglossum St. George var. solum.—A good spike of well formed flowers freely marked with chocolate maroon on a white ground, and with a golden crest. Award of merit to Messrs. J. and A. McBean.

SURPRISE GROUPINGS OF BULBS

THE element of surprise is always exciting and generally pleasing. To-day opportunity is knocking at our doors in the form of various small bulbs which may be used to tuck in here and there to form "unexpected" pictures in the flower garden. Wake your imagination and let it flutter round your garden, be it ever so small, and I will warrant that your journey shall not have been in vain and that the garden will be the richer by many and many an unexpected surprise picture that will peep out in the spring days, when you had all but forgotten the wee bulbs you buried.

Here is a large piece of rock at the corner of a pathway on the north side of which are two tufts of the wonderful Shooting Star of America (*Dodocatheon*). No sunshine ever burns their roots, and every spring they push out their little tufts of leaves, from the centre of which, before May has passed, springs a stalk carrying a tuft of rose or white or purple flowers. Beneath that Mock Orange bush the ground is filled with tubers of *Anemone apennina*, which never fail to carpet the earth, before the shrub puts on its leaves, with a mass of stary blue flowers equalled by nothing else. I cannot explain how that clump of *Allium Ostrowskianum* became allied with the white garden Lily, but there it is, and the "unexpectedness," when it pushes up its large umbels of reddish purple in early spring, is so charming that I would not move it for worlds. It is so safe, too, for everyone knows that the Madonna Lily must not be disturbed, and so the *Allium* is protected from destruction by a careless wielder of the spade.

The old Rose arches were becoming insecure, and "struts" had to be put in to secure them against winter storms, and these provided just the little home where wee bulbs would be secure, for, analogous with the case of the Lily, no one ever digs right up against a support, and so a safe harbour and ideal homes exist for small tufts of chequered Snakesheads, *Brodireas*, *Cyclamens*, *Muscari*, etc. There they grow and increase, taking nothing from their neighbours, secure and safe themselves, and contributing many and many a dainty surprise to visitor and owner alike.

Then, too, there are the alternate and combination plantings—altogether "unexpected" except to those very familiar with the garden. Possibly I ought to explain the terms more in detail. What do I mean by an "alternate" planting? Well, let us suppose two kinds of bulbs, say, Winter Aconite and Blue Muscari. These are planted in equal mixture alternately, so that early in the year, when winter has scarce relaxed its grip, there is a little patch of vivid gold, cushioned in flat, much-divided green foliage, while, considerably later, another flower picture is presented on the same space of ground by the stiffly up-standing spikes of blue Grape Hyacinths. "Combination" planting is a variation of this. Two kinds of bulbs are used and planted in a precisely similar way, but chosen so that flowering synchronises. Thus the golden Jonquil would be seen intermingled with the white Star of Bethlehem.

Close against the edge of a gravel path is another good "unexpected" bulb home, and I know a garden where, each February and March, every inch of pathway is outlined in gold, purple, mauve or white Crocuses. A gorgeous sight indeed! where on sunny days bees in myriads hold happy revelry.

To my mind the "unexpected" bulbs which peep out from edge and corner and, in general, the surprise features of any garden are the ones

that linger long in memory and get the biggest welcome when they appear. The days that are coming are the great opportunity offered us to

create for ourselves studied "unexpected" little bulb-groupings that shall endure for—who can say how long? H. W. CANNING-WRIGHT.

THE KING OF THE ALPS

ERITRICHUM NANUM is what our Alpine climbers call "the King of the Alps" and what we, Roman-Swiss, call Blue Moss ("La Mousse bleue"). It grows on the highest altitudes, from 5,000ft. to 8,000ft., on granitic or limestone rocks, always in full sun and in dry positions. It is one of those plants everyone would like to have in their garden but with which very few can succeed. I saw some, however, twenty years ago, beautifully flowered by my late friend, Mr. Charles Ellis, at Frencham Hall in pans in a cold house, and I know some English amateurs who succeed with it very well. It even sometimes reproduces itself freely on their rockeries, but how rare are these successes! At Edinburgh Botanic Gardens Professor Sir Isaac Bayley Balfour shewed me once nice examples seemingly very healthy, and on the west coast it is here and there luxuriant in walls or rockwork. It dislikes stagnant moisture, however, and rots off very easily; hence it is wise in some wet localities to protect it with a sheet of glass. Here at Floraire we tried it in several places—in the wall, on the rockery, in pans, in Sphagnum and in pure sand. Best of all was the culture in a peat bed, as shewn in the accompanying picture. We have here what we

flowering as freely as they do in Nature. But they were growing in a cool greenhouse or frame. At Hindhead in Surrey Dr. Jenkin grows things like *Saxifraga bryoides* and *S. retusa*, *Androsace pyrenaica*, and *A.A. glacialis* and *argentea*, *Tulaspi rotundifolia*, *Azalea procumbens*, *Phyteuma hemisphaericum*, *Gentiana bavarica* and *G. verna*, *Phyteuma comosum*, *Anemone vernalis* and *A. sulphurea* in a cold frame with a sunny exposure as well, I thought, when I saw them last May, as on our Alps.

After all, I think that the best means of growing and succeeding with *Eritrichium nanum* in the British climate is to grow it in a wall or cliff facing south and to keep it dry—even very dry in winter—and to grow it in a poor soil.

The Alpen King is not such a rare plant as people generally are apt to think. I saw it last summer in the Maritime Alps above Nice in such abundance and luxuriance that at first sight I could hardly believe it was not a dwarf species of *Forget-me-not* (*Myosotis alpestris*). There it was at an altitude of more than 8,000ft. and only on primitive rocks; but in the Champorcher Valley (Vallée d'Aosta) it grows on the chalk at a height not exceeding 6,000ft., and is beautiful in colour and health. The plant grows all over the Alpine

ERITRICHUM NANUM IN THE "TOURBIERE" AT FLORAIRE.

call a *tourbière*, the base of which is irrigated by running water, the top being a bed of peat which drinks up the water, absorbing it according to the needs of the plants. In such a way the plant is never exposed to danger of rotting off, as it is watered from below and water is never spilt upon the plant. But that method of culture, good for our Continental climate, is useless for the damp climate of England. There it is necessary to struggle against excessive humidity by exposing the plant to the full sun to produce active transpiration. I saw in Yorkshire, at Scampston Hall, the most delicate and tender alpinists (*Pyrola uniflora*, *Androsace argentea*, etc.) growing and

chain, always on dry cliffs, in full sunshine, and in the purest light of the high Alps. In the Western Caucasus it ascends to 9,000ft., and is very abundant. A friend of mine brought me once from the highest summits of the Cordillera in North America some dried specimens of *Eritrichium* saying that the plant was very abundant there. The specimens were, in fact, of a very near species of *Eritrichium*, called *argenteum*, and given by Clements (see "Clements' Rock Mountain Flowers," page 119, and plate 21, Fig. 8) quite wrongly as an annual, since the plants I had in my hands were very old ones. HENRY CORREYON.

CORRESPONDENCE

THE TWELVE BEST SHRUBS.

MR. G. HARVEY'S suggestion is an interesting one, and lends itself to correspondence, but would it not be preferable to ask for a list of the twelve best hardy flowering trees or shrubs? It is difficult to differentiate between trees and shrubs, e.g., some might say the bole of a *Eucryphia* makes it a tree. I know one quite 24 ins. in circumference! Again, I do not see the object in the plants listed being "suitable for massing." Few people lay out really good groups, and some shrubs are most effective as individual plants. Some of the groups at Kew and the Arnold Arboretum are good, but space and selected plants are both necessary to get the best results.—SENEX.

[Probably most readers will agree with "Senex's" suggestion that value for massing is not essential in a shrub, especially in a large one, but perhaps our original correspondent was anxious to compile a list of the twelve best shrubs for massing! We must all agree with "Senex" that it is exceedingly difficult to draw a dividing line between flowering trees and shrubs, but we imagine our correspondent wished to exclude such things as *Laburnums* and *Robinias*, which grow to a considerable size. May we hope that "Senex" (a recognised authority) will send us his own ideas as to the twelve best flowering shrubs.—ED.]

THE correspondence on the twelve best shrubs is very interesting if only for its wide differences of opinion. I quite believe that if twenty experts were asked to name the twelve best shrubs we should find they had at least 100 among them. I like a yellow Rose, therefore Golden Emblem is a better Rose than Red Letter Day! For some years it has been part of my duties to shew visitors round a fairly extensive and up to date collection of shrubs, and it has been one of my chief aims to get their opinions on the various plants and also my order book shews very strong opinion for the following twelve: *Eucryphia pinnatifolia*, *Tricuspidaria lanceolata*, *Embothrium coccineum*, *Ceanothus floribundus*, *Olearia semidentata*, *Desfontainia spinosa*, *Erica australis*, *Cytisus Donard Seedling*, *Osmanthus Delavayi*, *Veronica Gauntletti*, *Leptospermum Chapmanii* and *Berberis Pratii*. These are closely followed by *Rhododendron Ascot Brilliant*, *Philadelphus Virginal*, *Rosa Moyesii*, *Viburnum Carlesii*, *Escallonia Donard Seedling*, *Forsythia suspensa*, *Cotoneaster bullata* and *Pieris formosa*. Now with this collection I should expect quickly to bump with the person who has lime, with the one that registers over 20° of frost, and with the one whose garden could not afford plants that would get very big. So we seem to be driven to the conclusion that there are no such things as the twelve best shrubs, for what would be a gem in Cornwall would be a farce in Manchester—handsome is as handsome does.—W SLINGER (of the Donard Nursery Company).

IN accordance with the suggestion that readers of THE GARDEN should give their views on this subject (page 507), I am sending you a list of the dozen shrubs which would be my choice were I to be limited to this number. Perhaps there is nothing out of the ordinary in the selection, but all are decorative, and all have been found hardy in a West of England garden on the side of a hill with a slope to the west but badly exposed to easterly winds. I have intentionally omitted shrubs with special soil requirements, such as *Rhododendrons*, and I have not included *Roses*, which to my mind are not in place in a mixed shrubbery, but had I to name one I should

vote for the beautiful Chinese *R. Moyesii*, as much for its splendid hips as for its blood-red flowers. The following is my list: *Lilac Mme. Lemoine*, *Spiraea Anthony Waterer*, *S. arguta*, *Ceanothus Gloire de Versailles*, *Berberis Darwinii*, *B. stenophylla*, *Deutzia crenata*, *Buddleia globosa*, *Leycesteria formosa*, *Forsythia suspensa*, *Cistus ladaniferus* and *Solanum crispum*.—R. E. H.

AS your correspondent remarks (page 507), it is no easy matter to make a selection of twelve good flowering shrubs, especially when these must be suitable for a light loamy soil. I agree with you, Mr. Editor, that *Eucryphia pinnatifolia* should most certainly be one of the twelve. My vote is given for the following eleven shrubs in addition: *Magnolia stellata*, *Deutzia crenata fl. pl.*, *Ceanothus Gloire de Versailles*, the Mexican Orange (*Choisya ternata*), the Pearl

vitifolium should be in all gardens, either in the open or on a west wall. It is difficult to leave out the flowering Crabs, Plums, Cherries and Azaleas.—TIM.

A NOTEWORTHY KNIPHOFIA.

THERE is a certain amount of magic in the word "garden." It sounds quite as stimulating to a real devotee as "rats" to a terror. So I thought when I saw the wonderful setting of brilliant flame-like flowers of *Kniphofia corallina* in full flower quite recently. The picture I send is by permission of Mr. J. Bradshaw, of The Grange, Southgate, where this most beautiful hybrid (*Macowanii* × *aloides*) has been in flower since July, successively throwing up its perfectly erect, brilliant coral red flower-scapes. It will continue until severe frost. It is evident that *Kniphofias* are deservedly becoming more popular, providing as they do charming effects during the dull days of autumn and early winter, especially if undisturbed and allowed to form clumps.

MASSSED SPIKES OF KNIPHOFIA CORALLINA.

Bush (*Exochorda grandiflora*), *Pieris floribunda*, two *Berberis*, *B. Darwinii* and *B. stenophylla*, a small group of *Rhododendron* *Doncaster*, *Spiraea aristata* and *Escallonia macrantha*.—ROBERT H. JEFFERS, *Edinburgh*

IN reply to Mr. G. Harvey (page 507), I beg to enumerate what I consider a very desirable dozen. They are: (1) *Rhododendron campylocarpum*, pale yellow; *R. Loderi*, white; or *R. Thomsoni*, crimson—according to colour. Pink Pearl is nowhere with these masterpieces of Nature. (2) *Rosa Hugonis*, yellow; *R. altaica*, pale yellow; or *R. Moyesii*, superb crimson—according to colour; (3) *Buddleia globosa*; (4) *Cytisus scoparius Andréanus*; (5) *Eucryphia pinnatifolia*; (6) *Halesia carolina*; (7) *Magnolia parviflora*, *M. stellata* or *M. Lennei*; (8) *Syringa Souvenir de L. Spath*; (9) *Ceanothus Gloire de Versailles*; (10) *Philadelphus Virginal*; (11) *Escallonia Edinburgh*; (12) *Berberis Darwinii*. For a south wall *Chimonanthus fragrans*, and for a few dwarf shrubs *Viburnum Carlesii*, *Daphne Cneorum*, *Pentstemon Scouleri*, *Philadelphus microlepis* and *Azalea rosa-flora*. *Abutilon*

Kniphofias thrive best in a deep rich sandy loam, well drained and, if possible, on a raised bed where the drainage can be assured. Its grass-like foliage and flower-scapes are seen to advantage when planted in the foreground of a shrubbery border. Planting is best done either in spring or very early in autumn.—W. LOGAN.

COOKING SWEET CORN.

I THINK, possibly, the enclosed note on the cooking of Indian Corn may be interesting to your readers. The information is given to me by a Mr. Starr Truscott of the Navy Department, Bureau of Aeronautics, Washington, who told me that his mother knew more about the proper cooking of Indian Corn than any lady in the States.

"The most difficult thing is to determine just when the ear of Corn is ripe for plucking. Usually this may be known by the fact that the silky tassel at the tip of the ear is brown and dry, and the ear when grasped firmly feels solid and not cushiony. If the husk be stripped back for a short distance to expose a narrow strip of the grains on the ear, the grains should show completely filled out and

plump. If pressed by the tip of the fingernail, the skin should break easily and a milky juice appear. When the grain is tough under this test, the best stage for eating has passed. If the husk is pulled back and the grains found immature, simply straighten it back and wait.

"When ripe break the whole ear from the stalk by grasping it firmly and breaking the ear stem near the ear. Remove the husk and the fine 'silk' which lies along the grains.

"Use a rather deep kettle if possible. Place at the bottom a pad made of the inner layers of the husks. This should hold the ears, when placed on it, about 3 ins. up from the bottom. After putting the ears in, pour in boiling water until it just touches the lowest ears. Cover the kettle and boil for fifteen minutes to twenty minutes according to size of ears. (Small ears like Golden Bantam should take about fifteen minutes.) It

years old, and has never been known to do so before.—(Miss) E. GIFFARD, *Mont au Prêtre, Jersey, C.I.*

[The fruiting of *Akebia quinata* in Britain has been recorded from time to time, especially in the Southern and Western Counties, but it is far from common. The fruits are greyish violet in colour, cylindrical in form, with rounded heads, not, dissimilar, in fact, to those of some of the so-called Egg Plants (*Solanum Melongena*).—ED.]

AN ENGLISH THISTLE.

THE accompanying illustration is of *Cirsium eriophorum*, Scop, sub sp. *anglicum*, Petrak. It may be interesting to mention in these columns that the Woolly-headed Thistle of England (it does not grow in Scotland or Ireland) has been designated sub species *anglicum* by Dr. Petrak of Czecho-Slovakia in his Monograph of the genus.

THE UNCOMMON ENGLISH THISTLE, *CIRSIUM ERIOPHORUM* VAR. *ANGLICUM*.

will be noted that the process is really steaming, and a steamer may be used if available.

"There have been many ways proposed to make the method of eating more elegant, but all good Americans who really like Sweet Corn prefer to eat it 'from the cob.' This means simply 'gnawing' the grains off the cob, holding the ear by the ends. A little butter with salt and pepper spread on the ear at the point of attack makes the dish complete. The grains may also be separated from the cob by slicing them off with a knife, collecting them on a plate. This produces a dish resembling the American 'canned corn.'"—PETER R. BARR.

UNCOMMON FRUITS

THE pretty Japanese climber *Akebia quinata* grows and flowers very well here. This year, owing doubtless to last summer's abnormal sunshine, one branch that has grown away from the main plant (made very bushy by constant cutting back) has fruited, and the fruit shows every sign of ripening. Is this fruiting unusual? I should be very glad to hear of other cases of this climber fruiting. The plant I am writing of is over thirty

By special request I collected and dried a large number of specimens of this very prickly and handsome Thistle for the "*Cirsiothea*" which Professor Petrak has been forming, and which in due course will be distributed. The photograph is one of several taken on August 21 on a steep slope of rough pasture resting on Lower Lias between Bristol and Bath, where the plant is very abundant, as it is sometimes on similar ground in other parts of Somerset, but it is absent from Devon and Cornwall. The root-leaves form very handsome rosettes, and some of the largest leaves were just 3 ft. in length. The Thistle is biennial. H. STUART THOMPSON.

EUONYMUS JAPONICUS FLOWERING.

I AM unaware if it has been put on record that the common fleshy-leaved *Euonymus* of gardens, and especially of seaside gardens and promenades, has flowered profusely this year. Several of my friends in different parts of Southern England have had a similar experience with myself not having previously observed it in blossom. I have seen many bushes in flower or bud about Bristol, in Dorset and at Minehead.—H. S. T.

TRIALS OF NEW ROSES

Foreign Introductions of 1920.

THE new foreign Roses of 1920 bear little comparison with those produced in this country so far as can be ascertained from one year's trial. There are a few novelties and others are worth watching for the result of another year, but on the whole very few of them are likely to find their way to official recognition here.

Cornelia (H.T., Robert Scott and Son).—A clean medium grower with nice foliage, but the blooms are not satisfactory, being white, diffused with pink, and rather flat. A free bloomer, however.

Evrard Ketten (H.T., Ketten Frères).—Not a vigorous grower. A carmine red resembling Laurent Carle in colour, with the same failing of turning blue on maturity. Its best point is its fragrance—the good old red rose scent, and plenty of it.

F. L. de Voogt (H.T., J. Timmermans).—Strong, erect grower, with good trusses of thin yellowish pink blooms. A free bloomer.

Geisha (Pernetiana, G. A. von Rossem).—Yet another sport of Mme. E. Herriot, the growth being exactly similar. The blooms are flat and deep sulphur yellow in colour, but they hang their heads just as their parent. Sweet scented.

Glory of Steinfurth (H.T., Schultheis).—Origin Frau Karl Drusehki General McArthur. The growth resembles the former, but is not so strong. The blooms are large, deep pink in colour, and with the scent of General McArthur.

Irene Bonnet (Climbing H. T., G. Nabonnand).—This has not bloomed here yet, but has made good growth. It is described as being rose pink in colour and fragrant.

Jacotte (Wichuriana, Barbier et Cie).—This also has not yet bloomed, but growth is excellent. Described as a hybrid of *Rosa Wichuriana* × *A. R. Goodwin*, and coppery salmon in colour.

Juan Quevado (H.T., M. Leenders and Co.).—Fair growth. Very pale yellow blooms, with deeper centre. Not a good shape; too flat, but very sweetly scented.

Julia Bartet (Pernetiana, Barbier et Cie).—A moderate grower with big trusses of bright yellow blooms. Type of Mme. E. Herriot, but the blooms come small, and there are already plenty of bigger and better varieties on the market.

La Joconde (Pernetiana, J. Croibier et Fils).—A sport of *A. R. Goodwin*. Very weak grower, with small yellowish blooms edged pink. Sweet scented, but not a free bloomer.

La Rosee (Dwarf Polyantha, E. Turbat et Cie).—This is quite a novelty, and a good one. The growth is excellent, a continuous bloomer, the second crop being out before the first blooms were over. Light sulphur yellow blooms, the backs and edges of petals splashed red almost like a picotee edge. A distinct variety and worth growing.

Le Loiret (Dwarf Polyantha, E. Turbat et Cie).—An erect-growing and strong Dwarf Polyantha. Bright rose-red blooms in dainty—not heavy—trusses.

Limburgia (H.T., M. Leenders and Co.).—A strong grower, very similar to *J. L. Mock* in shape and colour. A "too-much-alike" variety.

Lodewijk Opdebeck (H.T., M. Leenders and Co.).—Very weak and thin growth. Red blooms which turn blue, and a very shy bloomer, too.

Mme. P. Doithier (H.T., C. Chambard).—Also a weak grower and a late bloomer. Resembles Mme. Abel Chatenay, but the blooms are flatter

Mme. Pizay (H.T., C. Chambard).—Erect grower. Blush pink blooms, cup shaped, but they get dirty. An undesirable new Rose.

Mme. Victor Rault (H.T., J. Croibier et Fils).—A good grower, erect and with heavy trusses of bloom. The latter are yellowish pink colour, globular in shape. A promising bedding Rose, with good foliage and a free bloomer.

Marie Lunnemann (H.T., J. Timmermans).—Origin, Pharisæer × Laurent Carle. Medium grower, but fairly erect. Blush pink blooms—nothing striking.

Merveille des Jaunes (Dwarf Polyantha, E. Turbat et Cie).—Not a strong grower. The blooms are rather unique in colour—copper with bright red edges, opening out reddish copper. The colour, however, washes out in wet weather. Small clusters of bloom, not heavy heads. Worth trying.

Mevrouw C. van Marwyk Kooy (H.T., M. Leenders and Co.).—Were it needed, the name of this Rose would prevent its ever becoming popular. An erect, moderate grower. Large white blooms slightly tinted blush.

Paul Lafont (H.T., P. Guillot).—A thin grower, but promising. Blooms are white with a deep yellow centre. Worth trying another season.

Pilgrim (H.T., A. Montgomery).—Not a strong grower. This variety also resembles J. L. Mock, but blooms are not so heavy. Sweet scented.

President Poincare (H.T., Grand Roseraies du Val de la Loire).—Origin Caroline Testout. Dora van Tets. Strong grower, with small globular blooms, deep pink with darker centres.

Souvenir de Claudius Denoyel (H.T., C. Chambard).—Origin Château de Clos Vougeot. Mme. Jules Gravereaux. The growth is good, but blooms are poor. Deep red and very flat.

Souvenir de Claudius Pernet (Pernetiana, Pernet Ducher).—Very strong and upright grower, with excellent foliage. Large bright yellow blooms of good shape. Sweet scented and a free bloomer. Quite one of the best of M. Pernet Ducher's productions.

Souvenir de Gilbert Nabonnand (Tea, G. Nabonnand).—The only new Tea Rose of the year. A good grower. Small blooms, deep yellowish cream colour, edged with red. Good foliage and sweetly scented. A free bloomer.

Souvenir de Mme. Augustine Gillot (Pernetiana, F. Gillot).—Origin Frau Karl Druschki. Lyon Rose. Very vigorous grower, but should rather be described as a Hybrid Perpetual than a Pernetiana, for the growth resembles its Druschki parent. Pale pink blooms, big enough for exhibition.

Souvenir de Mme. Morin Latune (H.T., P. Bernaix).—Thin, erect growth. Blooms resemble Ophelia, being light salmon with deeper centre, and good shape.

Victor Teschendorff (H.T., Ebeling).—Origin Frau Karl Druschki × Mrs. Aaron Ward. Medium growth, but excellent blooms, resembling Florence Forrester. An exhibitor's Rose.

Violincelliste Albert Foures (H.T., J. Croibier et Fils).—Strong, erect growth, with big trusses. Deep orange-coloured blooms of Mme. Ravary type. A good Rose for massing in a bed. Sweetly scented.

William Thompson (Dwarf Polyantha, M. Leenders and Co.).—Good growth and clean foliage. Large bright pink blooms, but they turn blue. An unwanted variety.

Of the bedding Roses undoubtedly the best is Souvenir de Claudius Pernet. Some of the others may improve upon acquaintance, but many of them will expect little further recognition or even remembrance.

In one direction, namely, the production of new Dwarf Polyantha Roses, our foreign friends

seem to excel, and there is still room for additions, especially in real yellow varieties.

The only new Tea Rose of the year 1920 is a foreign production, but it is unfortunate that it is not a more worthy specimen of its race.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Asparagus.—As soon as the growths are well matured they may be cut down, and the beds and alleys cleared finally of weeds for the autumn. Should it be the practice to use farmyard manure on the beds at this season, it should be so well decayed that it can be lightly pricked into the surface, for it is not a good plan heavily to top-dress the beds during the winter months, as it tends to keep them cold. Take the opportunity at this time, unless the alleys are still occupied with catch crops of other vegetables, to dig them well, using plenty of manure, as some of the fine rich soil thus made will be excellent dressing for the beds in the spring. The digging of the ground is also very beneficial as an aid to good drainage for the beds, an important point in successful Asparagus cultivation.

Salads.—Where there is a constant demand for these at all seasons, it is absolutely necessary to devote a number of cold frames to keep up late autumn, winter and early spring supplies. Given a favourable season and a warm soil, the supply of Lettuces and Radishes may be fairly easily arranged outside until December, but it is an uncertain yield later without frames of some sort. Any large plants of Lettuce and Endive growing in open positions where it is not convenient to give skeleton frame protection should be carefully lifted with good balls of soil and be accommodated where a covering can be given as necessary. Continue the blanching of batches of Endive as requirements demand either by the use of inverted pots outside or by removing the plants to a Mushroom-house or cellar. Mustard and Cress should be sown in heat every ten or twelve days, allowing the Cress about three days longer for development than the Mustard.

The Flower Garden.

Bulbs.—The planting of Tulips and Hyacinths may be done as early in November as convenient. They are both admirably fitted for mixed planting, also for associating with other spring-flowering plants, particularly Forget-me-nots, Arabis and Silene, each of these making an effective ground-work as a setting for their bulbous associates. In making a selection of Tulips and Hyacinths for the chief beds and borders it is better to select, as far as possible, varieties of proved merit. As a general rule those Tulips catalogued as bedders are more extensively used than the Darwins, but the latter should also be largely used when the spring beds are to be kept gay as long as possible. As an example a border of blue Myosotis may be interplanted with Queen of Pinks, or Proserpine perhaps, also with Clara Butt or Baronne de la Tonnyaye. The use of the Darwins will give the Forget-me-nots an added charm for several weeks longer than when only the so-called bedding Tulips are used. In the preparation of the soil for the bulbs avoid using new manure; burnt refuse and bone-meal are both good. Unless the soil is cold and retentive, Tulips and Hyacinths require from 4ins. to 6ins. of soil on top of the bulbs, while the distance from each other may be anything from 6ins. to 12ins., according to the nature of the groundwork and effect desired.

The Hardy Fruit Garden.

Top-Dressing.—The operation of top-dressing Peaches and Nectarines, although perhaps not often carried out, may sometimes be done with much advantage. It may be that the trees have carried quite satisfactory crops but show signs of exhaustion in some way or other, or the fruit may perhaps have hardly realised anticipations. In either case a good top-dressing will prove beneficial, inasmuch as the increased vigour given by aiding the development of fibrous roots by the top-dressing will greatly assist to maintain the trees in a continued state of fruitfulness. Before putting the new soil into position loosen some of the old surface soil carefully with a fork, removing a little of it at the same time; then lightly prick up the under surface, as this will

enable the roots to get a quicker grip of the new compost and also allow of the new soil being firmed into position better. A suitable top-dressing should be chiefly good loam to which has been added some wood-ash, old mortar rubble and some bone-meal at the rate of a 6in. potful of the latter to each barrowful of loam, and an 8in. one of wood-ash and a good shovelful of rubble. Get the work done as soon as possible so that the new roots can get a good hold of the soil before winter, and if the weather be dry give a good watering to resettle the whole.

Oxley. HERBERT L. WETLERN.

H. TURNER
(Gardener to the Duke of Northumberland).
Atbury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

General Work.—The clearing away of spent crops should receive close attention, as it is neither good for the ground to be carrying decaying vegetation, nor yet does it tend towards tidiness. Therefore have all Cabbage, Cauliflower and Turnip leaves placed in the rot-pit, where in time they will turn into useful manure. The haulm of Potatoes, Peas and Beans is best burned, as is also much of the other spent material in the garden, the ashes of such being rich in potash and proving a valuable fertiliser. These ashes are well worth taking care of, and should be stored under cover or used at once where digging operations are in progress. Take the opportunity during dry weather to wheel manure on to the ground that has been cleared so that the work of digging and trenching may be proceeded with during favourable weather.

Leeks.—Draw the soil slightly up towards the plants and thus assist the blanching process. This is particularly desirable for late lots which were not planted so deep as those for the principal crop.

Autumn-Planted Cabbage.—The excessive wet experienced in northern gardens during the last two months has been against the welfare of this crop, many blanks having been caused by the ravages of slugs. Make good the losses and run the hoe through between the lines; this aerates the soil and checks the growth of weeds.

Brussels Sprouts.—Remove all decaying foliage from the plants and encourage a healthy growth so that firm Sprouts of high quality may result.

Onions that have been ripened thoroughly may now be stored in quarters where they will keep in good condition during the winter. The value of medium-sized Onions has been further exemplified this season, being more easily ripened and keeping in usable condition longer than those of larger size.

Fruit Under Glass.

The Orchard-House.—All pot fruits will now have been cleared of their crops, but the trees must in no way be neglected in regard to moisture at the roots. Much of the trouble in regard to the dropping off of the buds may be traced to neglect in watering at this time. Keep the syringe going freely until the leaves fall, as this helps to keep insect pests in check. Allow full ventilation both night and day.

Pot Vines that have been standing out of doors should now be pruned back to the desired length and placed in a cool house until required for forcing. Dress the wounds with styptic.

Late Grapes should now be of sufficient ripeness to allow of artificial heat being considerably reduced, maintaining only enough warmth in the pipes as will keep the atmosphere in a buoyant condition and damp from condensing on the berries. This will ensure the bunches keeping in good condition. The danger is that, should too much fire-heat be used, the berries will shrivel. During fine weather air may be admitted freely, reducing it to a chink at night. The bunches must be examined regularly at this time and any decayed berries removed at once.

Promptitude in regard to this will often prevent the loss of the whole bunch.

The Flower Garden.

Bedding Plants.—Boxes containing cuttings of bedding Geraniums should now be placed under glass. If moderately heated pits are not available, they may meantime be placed in vineries from which the fruit has been cut. Pick off all the dead leaves before housing and allow plenty of space to keep the plants from becoming drawn. Ageratums, Heliotropes, Lobelias and Cupheas require rather warmer quarters, as they suffer readily from damp.

Planting Roses.—Where it is intended to plant Roses this autumn the ground should be prepared without delay. As the plants are not likely to be disturbed for several years, the soil should receive a generous preparation. The most suitable soil for Roses is a rich loam. Light, sandy or gravelly soils are not so suitable, but may be improved by taking out a quantity of the natural soil and adding good rich heavy loam. When trenching the ground dig in plenty of well rotted farmyard manure, but do not allow the roots to come into immediate contact with it when planting. Roses may be planted during favourable weather at any time from now onwards to the end of March, but from the last week in October till the end of November is best.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Hardy Shrubs for Forcing.—There are a large number of beautiful hardy shrubs that are most useful for furnishing the conservatory during the spring months. Many of them can be purchased specially prepared for forcing, such as pot-grown Lilacs. Others, such as Azaleas, Rhododendrons, Pyruses, Prunuses, Kerria japonica, Spiraea van Houttei and *S. prunifolia* var. fl. pl., to mention a few, can be lifted from the open ground at this time, and if placed in pots and tubs may in due course be successfully used for forcing. Instead of throwing the plants away, as is too commonly done after forcing, most of them can be used for a number of years. If they are planted out in the reserve garden for two years to recover and by using them in rotation one can have a regular supply each year. While it may be necessary to purchase some plants, there are others that can easily be propagated by means of cuttings, *Deutzia gracilis*, for example, and *Forsythia suspensa*, but the best *Forsythia* for this purpose is *F. intermedia* var. *spectabilis*, which with slight heat can be had in flower just after Christmas. This plant produces deep golden yellow flowers in wonderful profusion, and in an ordinary conservatory keeps in good condition for several weeks. A forced plant affords a ready means of propagation, as the young soft shoots root very readily. This also applies to many other shrubby plants used for this purpose. Azaleas and Rhododendrons with their restricted root system are well adapted for forcing, as it is a fairly easy matter to get them into moderate-sized pots. When using Azaleas and Rhododendrons for this purpose preference should be given to such varieties as naturally flower early, as they, of course, respond more readily to forcing. *Rosa Mundi* is a dwarf free-flowering variety that may be had in flower by Christmas; while *R. praecox*, often cut by frost outdoors, is very charming for indoor work. The latter plant is very free-flowering, and I have frequently forced this species for three and four years in succession. *R. Prince Camille de Rohan* is also good; in fact, most of the hybrids with caucasian blood in them force readily. Pink Pearl and the newer Alice are also excellent for pot work. Rhododendron *Kaempferi* in a number of beautiful varieties is excellent for forcing, and it is surprising that this plant has been so long neglected for this purpose.

Viburnum Carlesii is very charming for the conservatory, its fragrant flowers coming pure white when grown indoors. It will not stand hard forcing, and is best brought on in a warm greenhouse temperature. It is also best pot grown, as it seems to resent too much disturbance at the root. Purchased plants are usually worked on the common *Viburnum*, and a sharp outlook should be kept for suckers which prove very troublesome. It is easily rooted by means of soft young shoots.

Wistaria sinensis is a beautiful plant for the conservatory, and is best when established in pots. Like the *Viburnum*, it must not be given too much heat, or else all the buds will drop off. One of the secrets of successful forcing is

gradually to accustom the plants to a high temperature, introducing them too suddenly usually ends in failure, although Lilacs and Azaleas will stand high temperatures with impunity; but, of course, they do not stand so well as when brought on under cooler conditions. After the plants are potted up they should be stood outdoors until such time as they are required, protecting the pots from frost by means of hay or ashes.

Funkia grandiflora, although hardy in warm situations, is usually so late in flowering that most seasons it gets cut with frost. For this reason it is well worth growing in pots for the unheated greenhouse. If grown in 8 in. or 10 in. pots it forms a handsome specimen with its large ornamental

foliage and beautiful white, sweet-scented flowers. *Funkia tardiflora* is another late-flowering species which is well worth growing in pots for a cool house. It is a neat-growing plant and produces its purplish-coloured flowers in great profusion.

Zonal Pelargoniums.—Although these plants may be had in flower more or less all the year round, they are never more valuable than when in flower during the winter months. At this time it is essential that they be given a light, airy position in the greenhouse and not be overwatered, as damp is fatal to them. As a dry atmosphere must be maintained, it is necessary to have some heat in the pipes during the night and during dull days.

J. COUTTS.
Royal Botanic Gardens, Kew.

OTHER PEOPLE'S TREES

IT often occurs to me how beautiful other people's trees are. Anybody's or everybody's trees are subjected to scrutiny, admired and noted mentally, without invidious feeling and without the owner being aware of it. I have examined the minutiae of all of them at one time or other and can recognise most of the species at a distance without handling a leaf. Some of them I can diagnose at a mile away and others at lesser distances, so that I never become a nuisance to anybody and no one has to cut down anything to prevent himself from being overlooked by the sightseer. The trees are a source of delight no matter to whom they belong, and under those circumstances they are as much mine as the air I breathe. I can use the latter, view the trees and enjoy them; and the lord of the manor himself cannot do more. I once heard of a servant who walked out into the grounds of his master, sat down upon a seat and imagined himself the owner of the place, but was disillusioned when he went home to breakfast. He was not a domestic, but lived in a separate house on the estate, which made the contrast seem the greater.

All are aware of the splendid assortment of trees available, but they are best represented in the tree nursery or the botanic garden. Except in the large private garden it is impossible to

accommodate a tithe of the trees actually in the country, so that the selection for gardens generally has several limiting factors. Space is limited, the trees must be easy to grow, and few being specialists, people seldom attempt searching for rare trees. Such as they grow they have made the objects of their choice, and their selections may be regarded as an index of their affections in the arboreal world. It is always a pleasure to see more and more really handsome trees getting outside the nursery and the botanic garden. Many of them are of ancient introduction, highly ornamental, easy to grow and therefore popular, which is the reason why they have outlasted hundreds of other introductions.

Of more showy or conspicuous trees the first to commence flowering are the Almonds, of which there are several colours. Flowering takes place in February or March. From that time onwards the flowering trees expand their blossoms in succession like a panorama to the eye of those who walk abroad at frequent intervals or view it from the top of a motor 'bus or any other vehicle. The Purple-leaved Plum usually opens its snowy blossoms in March before the bad weather has gone, so that frost or rain may spoil them and so prevent the production of the Cherry Plums, which are excellent for preserving. The display, even if short-lived, is delightful. The profusion

ALMONDS IN BLOSSOM IN KEW GARDENS.

of blossom of *Pyrus floribunda*, *P. f. atrosanguinea* and *P. f. purpurea* cannot fail to arrest attention, and all are finest or deepest in colour when the buds are half expanded. The fruits set well in some seasons, and the tiny crabs are highly ornamental in autumn. Few of the fruiting Crabs are more ornamental than John Downie, the fruits becoming showy in late summer.

During their season nothing is finer than the double Cherries, and first place may be given to the double Gean (*Prunus Avium flore pleno*), every branch of which becomes covered with a mass of the purest white flowers, which last a long time in perfection. The Gean is a British tree, and the double one has been in cultivation for about two hundred years. The double Morello Cherry with the small green heart is less showy, though a beautiful and smaller tree. The most popular of the Japanese Cherries is *P. serrulata flore pleno*, with large double pale rose flowers, this being the oldest and best known introduction.

The darkest and finest of a large group are James H. Veitch and Hisakura, with large deep rose pink flowers. The Rose-bud Cherry (*P. pendula*) cannot be overlooked, for the deep rose, half-opened buds at the end of March are very striking on the umbrella-shaped tree. The Bird Cherry (*P. Padus*) and its small-flowered variety (*P. P. parviflora*) have been fine this year, as usual, and attracted the eye by reason of their long racemes of white flowers, drooping in the former and erect in the latter.

In April or early May the large white flowers of *Magnolia Soulangeana* easily take pride of place in many gardens. It is the most popular *Magnolia* in Europe, because it flowers freely and escapes frost when *M. conspicua* may get injured by flowering earlier. The paler *M. Alexandrina* is a less common tree. The evergreen *M. grandiflora* blooms all the summer and autumn, but many growers get impatient for it to reach the flowering stage. This could be overcome by selecting *M. g. exoniensis*, which blooms at an earlier age.

The Lilacs make a short-lived display in drouthy seasons like last spring, and commence the display with the old white *Syringa vulgaris alba*, followed by the ordinary Lilac and then others in great variety, of which the deep purple *Souvenir de Louis Späth* is the finest of the dark purple varieties. The best varieties, single and double, are not so well represented as they might be.

The Hawthorns or Mays are a host in themselves, but the most popular of all and the best is Paul's Double Scarlet Thorn, which was put into commerce by the late Mr. George Paul about seventy years ago. There is no need to urge the beauty of this variety, because it is the best among the

large group, every one of which is worth growing. This one sometimes gives rise to sports, and branches bearing double deep rose flowers, like *Cratægus Oxyacantha punicea plena*, appear on it. The double rose and double white varieties are also valuable because they remain longer in

JAPANESE CHERRY (*PRUNUS SERRULATA*).

bloom than the singles. All these Thorns, as well as other trees, bloom earlier in towns than outside of them, hence the advantage of going to the country occasionally. Soil and surroundings have a marked effect in giving an early or a late display. The Fiery Thorn becomes a mass of creamy white in late May and June, but it becomes irresistible in autumn when the red berries ripen. *Cratægus Pyracantha Lalandi* has larger, more orange berries than the type and is the finer of the two. Most of the trees, bushes and wall plants in some districts are now of this variety.

The popularity of the common Laburnum may be gauged by the immense number of trees to be met with in a day's journey. The racemes of flowers vary in length from 2ins. to 6ins., showing that the trees have been raised from seeds. The same applies to the Scotch Laburnum, which blooms two or three weeks later than the common one. It came into full bloom in many places this year at the beginning of June, when the faded blooms of the common species were littering the ground. For length of raceme and intensity of yellow blossom the Scotch Laburnum puts the other in the shade, resembling "dripping wells of fire," as the poet has it. Both species are necessary to prolong the display, though the late-flowering one is the finest, as anyone will admit who knows the two.

Contemporaneous with the late Laburnum comes the False Acacia, with its snowy trusses of bloom, the glory of which is enhanced in proportion to the size of the tree. The handsome rose-coloured variety (*Robinia Pseudacacia Decaisneana*) is rare, as is *R. P. semperiflorens*, which blooms

in a straggling way all the summer on the long shoots of the current year. *R. P. monophylla* is a curiosity, inasmuch as it leaves are reduced to one large leaflet, with one or two small ones occasionally. The narrow-leaved *R. P. angustifolia* and the golden yellow leaved *R. P. aurea* are also uncommon trees in private gardens. The Clammy Locust (*R. viscosa*) is rarely met with, but the Rose Acacia (*R. hispida*) is more common. Not so the variety *R. h. macrophylla*, which lacks the bristles clothing the branches of the type, and which is rare.

The common Horse Chestnut needs no eulogy from me, since thousands, perhaps millions, can testify to that. The English trees contain many among them richly blotched with red, such as are not found in some Continental countries. The finest red Chestnut is undoubtedly *Æsculus carnea*, a reputed hybrid between the common Horse Chestnut and the small red Buckeye (*Æ. Pavia*), the characters of both being evident in it. The Pavias have smooth fruits and leaves. Among them the yellow-flowered Sweet Buckeye (*Æ. octandra*) blooms contemporaneously with the False Acacia, and *Æ. purpurascens versicolor* has yellowish flowers, shaded with red or even heavily blotched with red on the inner face of the petals. The first named commences flowering when only 6ft. to 8ft. high, and is a delectable and distinct little tree.

The Mountain Ash is glorious in fruit, and the same may be said of the rare *Pyrus latifolia*, with its large yellow and orange-coloured berries in autumn. The Limes in July make the air redolent with their perfume. At the same time the Tree of Heaven becomes highly conspicuous when covered with its bronzy yellow bunches of keys. The Catalpas are late-flowering trees, the Indian Bean being the more common, while *C. ovata* is quite rare outside of large collections. Equally or more rare is the yellow-flowered and large-fruited *Kœlreuteria paniculata*, which blooms only in warm seasons, like 1911 and 1921, in this country. *Laburnum Adami* does not come into the same category for ornamental value as the two above named, but, being a graft hybrid, is a most interesting little tree, because after being grown some years, it almost invariably sports on branches into *Laburnum vulgare* or *Cytisus purpureus*, or both, which were the parents.

The above have all come under observation in one garden or another, but do not even exhaust the list of flowering trees, let alone the shrubs: while trees grown for the sake of their foliage chiefly have been omitted, with the exception of the Purple Plum and Tree of Heaven. J F

Trial of Late Culinary Peas at Wisley

THE following awards have been made by the Council of the Royal Horticultural Society to late culinary Peas after trial at Wisley:

First-class Certificate.—Ne Plus Ultra reselected, sent by Messrs. Carter.

Awards of Merit.—Autoerat, sent by Messrs. Dobbie, Messrs. Toogood, Messrs. Barr, Messrs. Watkins and Simpson, Messrs. Nutting and Messrs. Carter; and Freedom, sent by Messrs. Hurst.

Highly Commended.—Glorv and Perfection, sent by Messrs. Unwin; Passport, sent by Messrs. Hurst; Queen reselected, sent by Messrs. Sharpe; Glorv of Devon, sent by Messrs. R. Veitch; Wm. Richardson and Alliance, sent by Messrs. Kelway; and Goliath or Improved Mammoth Sugar, sent by Zwaan and de Wiljes.

Commended.—Dwarf Giant, Renown and Conquest, sent by Messrs. Unwin; Michaelmas.

sent by Messrs. Carter; Captain Cuttle, sent by Messrs. Pearson; Matchless Improved, sent by Messrs. Hurst; and Alderman selected, sent by Messrs. Dobbie

Meadow Saffrons.—At this season of the year when the summer flowers are fast fading a patch of fresh colour is a source of joy to all gardeners. Such a welcome sight is provided by Colchicums, flowering as they do at a season when flowers are much appreciated. The fact that they are low-growing rather enhances their value, for low-growing, autumn-flowering plants are not too plentiful. Colchicums, or Meadow Saffrons, to give them their good English name, will adapt themselves to almost any position, but thrive best in open, sunny places. They can be grown in grass, along borders, or on rockeries. The best effects are obtained by planting in masses, though heavy massing is not desirable on a rock garden; here, however, a good effect may be obtained by judicious selection of position. Owing to the fact that the leaves die down before the flowers appear, it is well, especially in the case of rock gardens, to plant the Colchicums where they will be best displayed by surrounding foliage plants. They can quite well be raised from seed; but as plants raised in this manner will not flower till the third year, it is usual to purchase bulbs, which should be planted in autumn. There are several species in cultivation, but most of the forms common in English gardens are varieties of *C. autumnale*. The largest-flowered species is *C. sperosum*. Though outwardly similar in many respects to the Crocus, the Colchicum differs largely in the shape of its leaves, which in some species are 12 ins. long and 2 ins. or 3 ins. broad.

For the Foot of a Warm Wall.—An attractive plant for flowering along a south wall is *Crinum Powellii* var. *album*. The pure white flowers are borne in umbels of eight, nine or even more on a stiff peduncle. With good treatment flowers measuring 4 ins. to 5 ins. across the trumpet may be obtained. The plant commences to flower in July and will in some cases continue sending out flowering buds until the early days of September. The long glossy leaves add to the attractiveness of the plant. *Crinum Powellii* is a hybrid between *C. longifolium* and *C. Moorei* and is one of the very few hardy Crinums. The bulbs should be planted about a foot deep in good garden soil. Away from the Southern Counties it will be necessary during the winter months to protect the plants from frost, for which purpose a layer of straw or bracken is usually sufficient.

For Bulbs and Plants.—The Editor recently received from Messrs. Richard Sankey and Sons, the well known flower-pot makers of Bulwell, Notts, samples of their ornamental pans in red pottery. These pans are made with or without drainage holes, as desired, and would be suitable for growing bulbs or, with drainage, for cultivating a wide variety of plants. Of agreeable form and pleasing colouring, these simple pans will make appeal to persons with real artistic feeling on account of their lack of meaningless "ornamentation," their beauty of outline, and entire fitness for the purpose in view.

FORTHCOMING EVENTS.

October 27 to November 4. The Imperial Fruit Show to be held at the Crystal Palace.

October 31. Royal Horticultural Society's Fortnightly Meeting. Lecture at 3 p.m. by Mr. C. L. Musgrave on "Methods of Propagation in an Amateur's Garden."

November 1. Croydon Chrysanthemum Society's Show.

November 3. Parsley Florists' Society's Meeting.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

ACANTHUS MOLLIS AND A. LATIFOLIUS (M. J. T.).—These two plants are botanically indistinguishable, being only forms of one species. *A. latifolius* (which means broad-leaved) is larger and more robust in all its parts, being very easy to distinguish by this means.

TREES AND SHRUBS.

BROOMS (Folsted).—The dry sunny bank described by our correspondent appears to be an ideal spot for Brooms. The best to raise from seeds sown now would be *Genista pilosa*, *G. tinctoria*, *Cytisus purpureus* and *C. Arduini*. *Cytisus kewensis* and *C. Beani* are beautiful prostrate Brooms, but as they are hybrids increase in size by cuttings.

YUCCAS AND OTHER QUESTIONS (A. M. T. R., Birtley).—Yuccas are hardy in most parts of the country. In cold winters and as a protection against snow, tie up the leaves tightly, holding them together with hay or straw bands. The loamy soil for Yuccas must be very well drained. This is best done by digging in plenty of old broken mortar rubble and other builders' rubbish. *Cedrus Deodara* and *C. atlantica glauca* are perfectly hardy. The only trouble with these would be the breaking of the branches with heavy falls of snow. The three *Magnolias* named (M.M. *stellata*, *complanata* and *Soulangiana*) are quite hardy.

PLANTING RHODODENDRONS (A. M. T. R., Birtley).—The best guide to the culture of Rhododendrons in our correspondent's neighbourhood is to visit the surrounding gardens to see if any Rhododendrons are grown and with what success. The treatment proposed should be quite satisfactory, including the top-spit soil where bracken thrives. Manure is not required for Rhododendrons; the only thing that might be beneficial is a top-dressing of very old spent manure after the Rhododendrons have been planted a few years. Wood ash would be beneficial and possibly a little charcoal if the soil is moist.

FRUIT UNDER GLASS.

VINES ATTACKED (E. W., Southampton).—During the winter, overhaul and disinfect thoroughly the whole house in which the vines are growing. Take off all loose bark from the vines and wash them with Gishurst compound. Thoroughly fumigate the house on the first sign of the pest with one of the advertised fumigants, and touch every mealy bug seen with a brush dipped in petrol or methylated spirit. Take all the other plants out of the house while the vines are dormant, if possible, and fumigate it thoroughly. If this is not possible, then a weaker fumigant must be used. For mildew, see that the ventilation is thoroughly efficient and that no draughts occur.

MISCELLANEOUS.

TRAPPING SLUGS (M. D. W., Ripon).—Slugs may be trapped by placing pieces of Potato, hollowed out, near their haunts and examining them at intervals to kill the captives, and the plants they attack may be protected by dusting with lime or by ringing round with ashes fresh from the furnace.

PACKING LILY OF THE VALLEY FOR EXPORT (E. S. M.).—Lift the crowns in the form of medium-sized clumps and place the latter in a dry, cool shed for at least one night prior to packing. Only remove any loose soil and not any leaves. Place a thin layer of coconut fibre quite dry in the bottom of a box just deep enough to hold the crowns, soil and leaves, and then pack the clumps quite close together, filling up tightly with coconut fibre before nailing down the lid. When unpacked simply plant the roots in a cool border, water once to settle the soil, and leave the foliage to die as naturally as possible. Do not remove it forcibly from the crowns. The check to the latter will not be great.

NAME OF PLANT.—Mrs. P., Bournemouth West.—Rose His Majesty.

NAMES OF FRUIT.—B. C.—The two Apples sent were such small, diseased and malformed specimens that it was impossible to identify them. The Bismarck Apple sent was not affected with mildew, but was attacked by the Scab fungus and aphides had also done some damage.

—E. B., Berks.—1, Cannot identify; 2, *Beurré de le Assumption*; 3, *Beurré Clairgaut*; 4, *Beurré Capiaumont*; 5, *Claygate Pearmain*; 6, *Autumn Pearmain*; 7, *Yorkshire Greening*; 8, *Golden Noble*.—T. S. T., Wincoboe.—Apples: 1, *Winter Hawthornden*; 2, *Royal Late*; 3, *Wellington*; 4, *Probably Blenheim Orange*, specimen poor; 5, *Saundersham*; 6, *Probably Brandley's Seedling*, specimen poor; 7, *Probably Rival*, specimen poor. —C. P. C., Apples: 1, *Queen Caroline*; 2, *Lord Burghley*. Pears: 1 and 2, *Marie Louise*.—T. F.—Apple *Homeade Pearmain*.—J. B.—Apples: 1, *Ribston Pippin*; 2, *Cellini*; 3, *Beauty of Stoke*; 4, *Allington Pippin*; 5, *Lady Renwick*; 6, *The Queen*; 7, *Charles Ross*; 8, *Golden Spire*; 9, *Bramley's Seedling*; 10, *Margil*; 11, *Emperor Alexander*; 12, *Manks' Codlin*. Pear: *Doymé du Comce*. —R. H. B., Fife.—1, *Gascogne's Scarlet*; 2, *Bismarck*; 3, *Annie Elizabeth*; 4, *Allington*; 5, specimen too poor to identify; 6, *Allington Pippin*; 7, *Summer Golden Pippin*; 8, *Lord Derby*; 9, *Probably Royal Late*; 10, Cannot identify, specimen too small and diseased; 11, *Ben's Red*. The labels had become detached from the remainder in transit.

VARIOUS USES OF ROSES IN THE GARDEN

THE English climate is particularly suitable for many classes of plant, but notably so for the Apple and the Rose. No wonder that the latter is our National Flower! It may be doubted, none the less, whether on the whole we use the Queen of Flowers to best advantage in our gardens.

The typical formal Rose garden is admirable enough in its way and displays fairly closely pruned dwarf-habited varieties to great advantage, but it is not the only way of using the so-called dwarf Roses satisfactorily. Such varieties as Hugh Dickson, Fellenberg, Boule de Neige, Mme. Eugène Resal, La Tosca, Pharisäer, Caroline Testout, Mermaid, Joseph Hill, Pax, Irish Elegance, Florence H. Veitch, Zéphirine Drouhin, Danæ and J. B. Clark will all, if allowed, grow into handsome bushes as wide as or wider than high and at least 4ft. to 5ft. tall. To these may be added *Rosa rugosa* in variety and most of the Rose species and such semi-climbers as Alister Stella Gray (which will make a magnificent bush 8ft. high and as much through), Grüss an Tephitz, Conrad F. Meyer, Nova Zembla, Lady Waterlow, Trier and Gustave Régis. Such almost naturally grown bushes are useful, of course, for the Rose dell or for informal gardening however named, but they have a real value in the more formal and ordered parts of the garden. On the Riviera, bush Roses are actually bushes, but in this country the very term is a misnomer, the consequence being that the great majority of gardeners scarcely look upon the Rose as being a shrub at all.

The Hybrid Sweet Briars almost without exception make charming bushes, but ample space should be left around them on account of their heavy armament of thorns. Meg Merrilies is probably, taking habit,

colour and freedom into consideration, the best variety, but the crimson-scarlet *Refulgence* is at once attractive and vigorous. The crimson and white *Janet's Pride* has many admirers, so—though it is not a Sweet Briar—has the rose and white *Leuchstern*. This is a variety of moderate vigour which never sheds its petals, a very unusual trait in a single Rose. It is excellent for bushes in the open or for Rose hedges. To return to our Sweet Briars, the most attractively coloured varieties are, of course, *Lord Penzance* and *Lady Penzance*, but not everyone can persuade them to make satisfactory bushes. Some of us, however, will keep on trying, for when they do succeed they are certainly very lovely.

The popularity of weeping standards has become so great as almost to amount to a craze. The cult of tall weeping standards has, indeed, been carried to absurd lengths, but those with "legs" not exceeding 4ft., or at most 5ft., are valuable as affording a variety not otherwise obtainable in specimen bushes, for so such trees may fairly be called when they have become almost solid

mounds of vegetation. Almost all the *Wichuraiana* hybrids are successful so treated, but mention may be made of *Albéric Barbier*, *Jersey Beauty*, *Klondyke*, *René André*, *Débutante*, *Gardenia* and *Troubadour* as especially suitable. The less substantial foliage of the *Dorothy Perkins* section renders them less valuable, but they, too, answer fairly well.

Rambler Roses, also, though used extensively—in the case of a few favourite varieties perhaps too extensively—are not always employed as effectively as they might be. They are used to far too great an extent for covering walls, where some of the choicer climbing varieties would succeed better and give incomparably finer effects. On the other hand, the Rambler section is far too seldom seen growing into and over trees. It is surprising how readily people will go to some expense and trouble to provide a more or less unsightly pole for a Rambler when labour and eyesore might be at once avoided by planting the Rose to climb a tree with, ultimately, far finer effect. The Musk Rose, *Rosa moschata*, is finest of all for climbing

through and flowering in the tree tops, but unfortunately even the hardiest forms are not recommendable for inland gardens in the North. The double Hybrid Musk, *The Garland*, is almost equally free and very considerably hardier. Most of the stronger-growing *Wichuraiana* hybrids are suitable for the same purpose, especially *Dorothy Perkins* and its relatives *Excelsa* and *Lady Godiva*. The multi-flora Ramblers, once so popular but now largely superseded by varieties having *Wichuraiana* blood, do not make sufficient continuing growth to be suitable for tree climbing, but they never shew to greater advantage than when planted in a shrubbery and allowed to throw their trails almost at

AMERICAN PILLAR, PERHAPS THE HANDSOMEST OF WICHURAIANA ROSES.

will over other shrubs. They serve, too, to provide colour in the shrubbery when it is none too plentiful. Any varieties belonging to the section will answer so treated, for they value the shady root-run, but perhaps the two best are Crimson Rambler, once so ubiquitous, and the really charming Blush Rambler. Other worthy sorts include the early-flowering and charming single Carmine Pillar, Hélène (a very strong grower), Goldfinch, Tausendschön and Tea Rambler.

Roses are to-day largely used for screens, Rambler varieties being trained for the purpose to a trellis or other framework. If the framework is made sufficiently stout, they answer the purpose quite well, especially where a wise selection of varieties is made. *Albéric Barbier* is especially suitable for several reasons. It has handsome dark green glossy foliage, is, in favourable situations and winters, evergreen, is a robust and "extending" grower so makes little dead or worn-out wood, and flowers more or less continuously from mid-summer until late autumn. Strained wire answers quite well for the training if the wire be of fairly stout gauge and well galvanised, and the straining posts be substantial and securely anchored. The strain caused by a considerable weight of Rose branches laden with snow is very considerable, and it is wise wherever possible to provide one length of rails running between the posts at the top to counteract the pull of the wires.

Rose hedges are often spoken and written of, but less frequently seen in gardens than their value would suggest. If a measure of protection is needed against straying cattle or other trespassers and a second line of defence is often useful—nothing better can be employed than Sweet Briar, either some of the more robust Penzance hybrids or the delightfully fragrant species itself. Such a fence may be reinforced if desirable, with posts and wire or chestnut spile fencing. Japanese (*rugosa*) Roses or the fragrant and altogether delightful hybrid *Conrad F. Meyer* may, if preferred, be used in a similar way.

If the hedge is to be purely ornamental, there is a great number of varieties from which a selection can be made, and any height may readily be provided from 2ft. to 8ft. The Scotch Roses, in variety are useful for hedges up to 3ft. in height, and this represents about the maximum practicable height of hedge of *Mme. Eugène Rosal*, *Irish Elegance* or *Fellenberg*. *Hugh Dickson* and *Gruss an Teplitz* will run to 5ft. or so, and *Leuchterstern* is most effective when headed back at about 6ft., while *Mme. A. Carrière* and *Alister Stella Gray* have an effective height of quite 8ft. *Mme. Carrière* is very free, handsome and fragrant, and *Alister Stella Gray* is surely, of tall-growing Roses, the most prolific and perpetual. Even in November bushes are often still smothered with the rather small orange buds and creamy blossoms. The elegant arching canes, handsome foliage, luridly brilliant flowers and glossy hips of *Rosa Moresii* make this perhaps the best of the species for hedges, though the hips or *Rosa Fargesii* are even more brilliant. The very pale yellow *Rosa altaica*, closely related to the Scotch Roses, is excellent for the purpose, and may be relied upon to reach 5ft. or perhaps a little more. The happily named *Moonlight* (Hybrid Musk) is also becoming popular as a hedge plant. The thornless *Zéphirine Drouhin* with its rose-coloured blossoms is another much prized for this purpose.

The standard Rose—the ordinary old-fashioned standard, not the newer "weeping" sort—is, properly employed, exceedingly useful and handsome. Too often, however, specimens are dotted more or less promiscuously about beds of dwarf Roses. Not is this all. Very frequently, even

WICHURAIANA ROSES OVER A ROUGH FRAMEWORK OF TIMBER.

WEeping STANDARD ROSES WELL USED.

PLEASING MOUNDS OF ROSE ELECTRA.

ABOUT SINGLE ROSES

when the general placing of the standards is good an unsuitable selection of varieties ruins the intended effect. Roses suitable for standards may be roughly divided into three classes, namely, those which form large heads, those which form heads of medium size, and the more usual varieties which form small heads. Obviously in a row of standards all should be of about equal vigour. Large growers include Gloire de Dijon, Grüss an Teplitz, Lady Waterlow, Mme. A. Carrière, Alister Stella Gray and William Allen Richardson. Smaller than these but still far more vigorous than the ordinary standard are General McArthur (admirable as a standard), Hugh Dickson, Joseph Hill and Gustave Régis. Of the ordinary run of standards the following are especially recommendable: Caroline Testout, Château de Clos Vougeot, Cynthia Forde, Ecarlate, George Dickson, Isobel, K. of K., Lady Ashtown, Lady Hillingdon, Lady Pirrie, Louise Catherine Breslau, Lyon Rose, Margaret Dickson Hamill, Mme. A. Chatenay, Mme. Ravary, Mme. Segond-Weber, Molly Sharmar Crawford, Mr. A. E. Coxhead, Ophelia, Pharisæer and Prince de Bulgarie. Standard Roses are seen to best advantage when used to form an avenue in rather restricted quarters where larger trees would be out of place or when utilised in single rows to balance a weightier feature on the opposite side of a pathway or vista.

The advent of the Wichuraiana hybrids made feasible the training of Roses down walls or unsightly banks, which is, in some cases, a great advantage. To take a typical instance, let us consider the question of the terraced garden which almost necessarily calls for a retaining wall with a parapet above ground level on the upper side. The material of which such a wall is composed should be good, perhaps shapely brick or more or less dressed stone. It is a thousand pities entirely to hide such a wall but, in a garden, it must obviously be draped. Now, looked at from below, an occasional slight mounding of vegetation on top of the wall with trails depending from it, is certainly preferable to the effect produced by climbers all starting at the foot of the wall.

It may be said that if there were no Roses of a more or less weeping habit of growth, there is an abundance of vines which would serve our purpose. This is so, but as the Roses do exist, let us use them and be thankful. Most of the Wichuraiana section are suitable for the purpose so far as habit of growth goes. American Pillar, which many consider quite the best of the section and which is illustrated on page 551, is an exception, the growths being too stout to hang with any grace. The Dorothy Perkins section answers on a wall with an easterly exposure (or with a westerly one if anyone can be found to devote this to such commonplace plants!), but they usually get badly infested with aphides on walls or banks at all sun-parched. Albéric Barbier is the great stand-by for such positions, but the beautiful single Jersey Beauty or the semi-double Klondyke answer well. Of the pinkish sorts, René André seems to withstand heat the best and of crimson the best is, undoubtedly, Troubadour, a variety which for some reason seems to have made little progress towards popularity. For banks the species itself (Wichuraiana) is extremely beautiful and useful. It has the great merit of quickly obtaining a foothold on the bank itself, thus staying any tendency towards crumbling.

The popularity of these Wichuraiana hybrids is understandable, but for pillars and suchlike the more compact growing, if older, multifloras have great advantages. There is no reason why both classes should not continue to exist side by side. The best of the Multifloras are Blush Rambler, Philadelphia Rambler, Mrs. F. W. Flight, Tausendschön, Leuchtstern, Aglaia and Thalia

I AM not burning my boats in writing this heading. I am just using language which my ten thousand fellow members of the National Rose Society understand. It goes a bit against the grain to put "single" in the title. How much, the above ten thousand may know by their feelings if on reading an article "On Rose Monstrosities" they were to find it was all about Lady Pirrie, Ophelia, Independence Day, Mme. Abel Chatenay, Gloire de Dijon and Zéphirine Drouhin—in fact, all about those endless varieties which a rosarian would ordinarily label "Roses." I had no idea how some people look down on single Roses until I paid a visit to

wrath on what he called "official love." It is a grand phrase. Not long since I had a silly woman looking at my Michaelmas Daisies. Does no one know what I mean when I say she gave them "tulsome 'official' admiration"? Thus, in writing in praise of single Roses, it is not that I wish to bring about a grudging official recognition of their charms either from superior individuals or from a thoughtless society. They are "when unadorned, adorned the most," and can very well be left to take care of themselves; but if people do not know there are such flowers, how is it then? There are both species singles, like Moyesii and nitida, and hybrid-singles like Isobel and

the climber American Pillar. But as climbing Roses are, as it were, a class apart, and as they have been freely admitted into very many gardens as *personæ gratae*, they may be left with this passing reminder of one of the best and most effective of all, although it is only a summer bloomer. Isobel is deservedly one of the most popular of all Roses at the present time. Many, however, seem unable to appreciate it when it is fully open, and write of it as if its beauty has well nigh departed when its "sweet seventeen" stage is passed and it has become a full-blown flower. Take, too, for example the sweet fresh pink Mrs. C. E. Salmon or the warm buff Mrs. Oakley Fisher, or that statuesque-looking white Innocence which Mr. Chaplin brought to the last autumn show. Can the fleeting girlish charms of even Los Angeles and Lady Pirrie compare with the more mature beauty of these singles? Were I to include semi-singles I would add to the three already named Rose Celeste, Moonlight and the Hon. Ina Bingham. How delicious the scent and how brilliant

THE "STATUESQUE-LOOKING WHITE" INNOCENCE.

a Rose friend who had many times asked me to come and see his garden. After I had seen almost everything we came to a bush whose flowers had but one row of petals, which surrounded a golden centre of stamens. Quite innocently I remarked that I thought it was the most beautiful Rose I had seen that afternoon. Oh my! wasn't the fat in the fire! Only the politeness of an English host saved me from an angry and forcible dismissal.

My friend is doubtless rather extreme in his views, but I wonder if it has struck people that there is not one class in the National Society's schedule for single Roses. Surely it is a bit hard upon their feelings to find themselves denied admission to the company of show flowers because they have never put on a sufficiency of skirts. At the late Church Congress at Sheffield a well known London clergyman poured out the vials of his

the colouring of the new Glowworm! I would like to be somewhere where its perfume is "very thick." It seems so Eastern-like. "Sure" then if I were to shut my eyes and, opening them, look around, I would find myself in that "bower of Roses by Bendemeer's stream."

How marvellous the deep carmine colouring of nitida's leaves and stems in autumn time! But neither scent nor deep autumn tints are the peculiar inheritance of single Roses, so perhaps it is a wee bit unfair to mention them at all; only, again, everyone may not know they are to be found among the singles. The unaccustomed rather loud double colouring of The Queen Alexandra Rose is not half so "polly" as that exquisite contrast which we find in the Austrian Copper—a true single. And to pass on to species singles. A big debt of gratitude is owing to those who

have brought us from China and elsewhere such delightful varieties as Moyesii, Hugonis, Willmottiae and some which I only know by repute or from seeing their features delineated in such pictures as are to be found among the pages of the "American Rose Annuals," as, for example, Gentiliana, multibracteata, bella, Jackii and multiflora var. cathayensis. It makes one's mouth water to think of them, and it goes without saying that the lover of single Roses would like to possess some of them. Where are they to come from? A quotation from the third volume of the "American Rose Annual" (that for 1918), page 27,

hits the nail on the head. "One drawback to the popularity of single or bush Roses is the difficulty of getting most of them. Many nurseries carry R R rubiginosa (the Sweetbriar is more attractive to the writer than the showier Penzance hybrids), carolina, lucida, nitida, setigera and rugosa. The others—dozens of them—are hard to find. Why does not some nurseryman stock up with every kind of wild and bush Rose he can find (perhaps he does already, unknown to the writer, in which case I think the Editor, who is a Rose crank himself, ought to give him a little free advertising), and why do not a hundred or a thousand make

collections as complete as possible if only to encourage him in his good work?" The argument is somewhat of a circular nature. The amateur must begin to form collections, presumably from the nurseryman's stock in trade which, when rung up, simply is not there; and the nurserymen must hold stocks for collectors who have still to be enthused. In our own Rose Annual for 1918 Mrs. Darlington and Mr. J. R. Ramsbottom both write in praise of Rose species. The seed has been sown. Let lovers of Roses water the tender plaut with words in season, and as opportunity offers proclaim their love. J. JACOB.

THE BEAUTY of the WILD ROSES

UNDER this heading it is possible to arrange a large number of wild or quasi-wild species, hybrids and varieties of Roses that appeal to many garden lovers on account of the beauty of their flowers, fruit or foliage, or the fragrance of their flowers or leaves. The list could be extended indefinitely, but a selection will afford variety sufficient to meet the requirements of most gardens, except those of the specialist. No class of plants is more variable in the wild state, and when brought under cultivation their possibilities are unlimited when subjected to crossbreeding or hybridisation.

The White Rose (*Rosa alba*) has been cultivated from time immemorial, although it is recorded in some books as having been introduced in 1597. Various countries of Europe and the regions of the Caucasus have been given as its native habitat, but most botanists are agreed that it is a hybrid. It has been found wild in France and elsewhere. It appeals by the fragrance of its white or blush flowers, one variety being largely cultivated for extracting attar of rose. In one form or other it is the glory of many a cottage garden, the varieties being represented by Rose Celeste or Celestial, Maiden's Blush and Jacobite White. A closely allied hybrid is *R. macrantha*, which enjoyed considerable popularity some thirty years ago. The blooms are blush fading to white, and measure 3 ins. to 4 ins. across. Another that figured prominently in floral decorations some years ago is *R. Andersoni*, with bowl-shaped rose pink flowers.

The Musk Rose (*R. moschata*) is represented in this country by the vigorous climber best known as *R. Brunoni*, which many rosarians term the Wild Briar of the Himalayas. This is seen at its best when given an old tree, of considerable height over which it can ramble and spread out its compound clusters of flowers, at first pale yellow, but soon changing to white. In a wild state it extends from South Europe to the Himalayas and China. Very numerous hybrids exist in

gardens, a goodly proportion of which are of recent origin. The Macartney Rose (*R. bracteata*) would be more often seen in gardens than it is were it only somewhat hardier. It is quite suitable for the South and West of England but, about London, is better for the protection of a wall. The leaves are dark green, leathery and evergreen, the latter character being, no

their size, structure and arrangement constitute a striking feature of this species, which in leaf and flower is unique in cultivation. Several hybrids have been produced in gardens, of which Mermaid is one of the most recent and striking on account of its large, pale yellow flowers. It can be grown as a bush or climber.

The most popular of the recently introduced yellow Roses is *R. Hugonis*, named after Father Hugh Scalan, who sent seeds of it from Western China to Kew, where it was reared in 1889. It forms an upright self-supporting bush for the first few years, and produces a profusion of bright yellow flowers about the middle of May onwards. It never becomes rampant, though it will ultimately get 8 ft. high and as wide, if not restricted. The leaves are not unlike those of the Scotch Rose, but larger, and produced in such quantity as to form a delightful bush. The Scotch Rose (*R. spinosissima*) is the first of our native Roses to open its creamy white, fragrant blossoms in May. Rare specimens are deep red, one having been found recently in Cheshire by Major Wolley Dod, who monographed the British Roses. The variety *R. s. lutea* bears buttercup yellow flowers 2 ins. across. Larger in every way is *R. s. altaica*, with creamy white flowers 3 ins. in diameter. All these forms make self-supporting bushes of great beauty. They are perfectly hardy and of the easiest cultivation. The first coloured variety was found in Perthshire, and that gave an impetus to the cultivation of this race till a very large number, probably hundreds of varieties, single and double, were named and put into cultivation. This gave rise to the name Scotch Rose, for the wilding is common to Britain. The beauty of the Austrian Yellow (*R. lutea*) cannot be over-

THE BRIGHT YELLOW FLOWERS OF ROSA HUGONIS.

doubt, the chief reason for its tenderness. The white flowers measure 3 ins. to 4 ins. across, and are surrounded at the base by several large, deeply cut bracts that invest the orange-red, woolly fruit. Most wild Roses have these bracts, but

looked, though so well known that a mention may suffice. The species is closely allied to the Scotch Rose, but differs in the absence of the bristly prickles that clothe the stems of the latter. It is the yellow parent that has given the Pernetiana

ROSES FOR CUT FLOWER AND INDOOR DECORATION

Roses their most striking characteristics. The Austrian Copper (*R. lutea punicea*) has given its two remarkable colours to Juliet and The Queen Alexandra Rose. All the above group only require thinning occasionally, but no regular pruning, for they bloom profusely on very small twigs.

The thornless Roses are not particularly common, although they have been long in cultivation. The bright pink flowers of *R. alpina* are followed by narrowly pear-shaped, deep red fruits. It has given rise to the Boursault Roses in cultivation. The Pyrenean variety (*R. a. pyrenaica*) is notable for its dwarf habit, sea-green hue and long, bristly yellow fruits. It takes up little space and is suitable for the rock garden. The Smooth or Meadow Rose is thornless, though it may have a few bristles on the stem occasionally. Many visitors have been charmed by its rose and deep pink flowers growing along the sides of the street or in the small front gardens of a central Highland village, often quite unprotected. It makes an upright bush about 4ft. high.

The long, bright red and pear-shaped fruits of *R. macrophylla* are preceded by clusters of large light red blossoms, and accompanied by beautiful foliage. This leads up to *R. Moyesii*, one of the most striking and interesting of recent introductions. The colour of the large flowers is difficult to describe, and has been called rosy red, reddish crimson, lurid dark red, deep red and terra-cotta red by various people who have attempted to define it. The bottle-shaped, red fruits are glandular and rough at the base. The species was accorded an award of merit by the Royal Horticultural Society when shewn by Messrs. Veitch in June, 1908.

A really splendid companion to this variety is *R. Fargesii*, which was honoured by an award of merit on October 17 when shewn by Mr. J. C. Allgrove. The fruits are 2ins. to 2½ins. long, bristly all over, and have longer necks than those of its relative. Even the sepals are fleshy and scarlet like the rest. In clusters of two or three, the pendent fruits resemble the tube and sepals of a scarlet Fuchsia.

The four-petalled Roses are notable for their tall, slender, upright growth and profusion of white flowers, produced singly and closely wreathing the long stems in May in advance of most other Roses. The best known is *R. sericea*, but this was followed by the Mount Omi Rose (*R. omiensis*) in 1901. The pear-shaped, red fruits have a thickened deep yellow stalk. The stems vary greatly in armature, and the most remarkable in this respect, *R. o. pteracantha*, has recently been placed under the Mount Omi Rose instead of under *R. sericea*. The young and growing stems are more or less covered with large, flattened, translucent blood red spines that make them appear winged and unique among Roses.

Many other Roses are noted for their large and handsome fruits, particularly the Ramanas Rose (*R. rugosa*) and the Burr Rose (*R. microphylla*), both with flattened, globular fruits, the last named resembling a burr in its bristly character, and green colour, to which fragrance is added. The Apple-fruited Rose has the largest of any, and is related to the British *R. mollis*, which is much dwarfer, perfectly upright and usually loaded with its handsome, globular, deep red fruits. The wild Sweet Briar has a variety with orange-scarlet fruits that are bristly all over; this is *R. rubiginosa echinocarpa*, that is, hedgehog fruited. *R. rubrifolia* is unique in its purplish red and sea-green foliage, reddish stems and deep rose flowers. It should certainly find a place in collections. The fruits, which are produced in bunches of some little size, are also attractive.

HORTICULTUS.

WITH the possible exception of the Violet, no flower gives so much pleasure when used for indoor decoration as does the Rose. Even the Violet itself can scarcely be called a serious rival, for though it holds a very high place in our affections on account of

flowers; and hence there was dissatisfaction among the competitors. Without a doubt many flowers are far easier to arrange gracefully and lightly than Roses are. Poppies, Sweet Peas, Carnations, to mention only three kinds, have slender, smooth stems which will easily be persuaded to stay just where they are wanted to

when cut and placed in water, whereas Roses have for the most part thorny, somewhat thick stems, and not infrequently they hang their heads and droop in an ungainly way. Those varieties which do this in a marked degree—for instance, the beautiful Tea, Mrs. Foley Hobbs—are really not suitable for cut flowers except in specimen vases or in exhibition boxes where the wiring they require is given them as a matter of course. But to my mind wiring Roses, or any other flower, for ordinary house decoration is much to be deprecated, for a wired bloom never has the grace or natural pose which goes far to make the beauty of a flower.

If only we choose the right sorts of Roses they will provide us with what we most want in our house decoration—colour, pure and varied; form of surpassing loveliness; and fragrance, refreshing as well as sweet; and to add to these attractions many varieties have singularly beautiful foliage.

Some may object to the Rose blossoms on account of their short life, and certainly the Rose does not

ADMIRABLE FOR CUT FLOWER, ROSE OPHELIA.

its unsurpassed fragrance, yet it has quite a limited range of colour and form, while the Rose in both these respects has almost infinite variety. We can fill small bowls and low vases with Violets in the spring and again in the autumn, but from May to November the Rose will give us sprays large and brilliant enough to be effectively used in tall epergnes and high standard vases, or small and delicate enough for tiny specimen vases. The comparison between these two flowers brings to our mind Sir Henry Wootton's verses:

"Ye Violets that first appear,
By your pure purple mantles known.
Like the proud virgins of the year,
As if the spring were all your own—
What are you, when the Rose is blown?"

The pre-eminence of the Rose as a cut flower is further proved by the fact that at many flower shows it has been found necessary to make a separate class for Roses when used for table decorations, because judges seemed unable to resist the beauty of the Rose even though it might not be so well arranged as some of the other

last so well as the Carnation. But many Roses bloom with wonderful freedom and continuity, so that though the Rose of to-day may be gone, the Rose of to-morrow quickly takes its place. And it is well worth our while to take a little pains with our cut Roses. In the first place, we should always cut them in the bud or half-open stage, and we should also cut them in the coolest part of the day. If before arranging them in the vases they are to nil, we cut off the thorns and scrape the stems and plunge them for not less than a couple of hours into basins or bowls, being careful not to let the petals actually touch the water, they will be able to take up sufficient moisture to make the stalks firm and the Roses will probably last two or three days even during hot weather, and, naturally, a day or two longer as the weather gets cooler.

There is no way in which Roses look more delightful than when arranged in bowls either of one variety or of mixed varieties. A few years ago one could go out in the garden and pick from many different sorts, then come in and arrange them together in a bowl with usually quite happy

results from a colour point of view. The pale and deep pinks, the crimson and maroons, the cream, yellow and buff shades would all blend harmoniously. But since the advent of such Roses as Mme. Edouard Herriot, Henrietta and others of terracotta and strawberry or orange tints we have to be much more careful. The exquisite glowing rose pink of Mrs. E. G. Hill loses all its brilliancy, and looks "blue" and dowdy if it is arranged with either of the kinds I have mentioned. For this reason I think the plan of arranging each variety separately has become more and more popular. Nothing looks better than a big bowl or vase of a brilliant crimson Rose with handsome dark foliage, such as Mrs. Edward Powell or Hugh Dickson, or for those who prefer light colours the glistening yellow Mrs. Wemyss Quin or the softer tinted and perfectly formed fragrant Ophelia.

Still, those who have the artistic sense and who love colour will not rest content with such simple schemes. They will find a fascinating occupation in arranging together Roses whose varying tints add to instead of detracting from one another's loveliness. A combination of Old Gold with

Severine or Emma Wright, or Red Letter Day with young blooms of Hoosier Beauty or Dora van Tets, or of some of the soft pink or pale flesh varieties may make very charming table decorations, especially if to be seen only by artificial light, for "colours seen by candle-light look not the same by day," and many Roses blend well even by electric light whose colours are not nearly so harmonious when seen by the white light of day. Such a Rose as Mme. Edouard Herriot will not always "go" even with itself! The intense flame colour of the young buds will clash with the distinctly blue tinge which sometimes appears unexpectedly on the open blossoms.

Those who have but little time to give to arranging their flowers will find the Dwarf Polyantha Roses useful. Their straight clusters of blossoms, for the most part with smooth stems, are very quickly picked and placed in vases. Little brown baskets arranged with the deep crimson Poly. Pom. Edith Cavell and the brightly tinted leaves of Rosa nitida make quite a pretty autumn table decoration which, while taking the minimum of time to arrange, will last fresh for many days. The

fern-like foliage of Rosa sericea, the four-petalled Rose, and the glaucous stems of Rosa rubrifolia are very decorative when used sparingly with some of the Hybrid Teas, and look far better than Asparagus or other Ferns which some are tempted to mix with their Roses.

The Rose is so glorious and complete in itself that it wants very simple treatment when used as a cut flower. Over-elaborate treatment and the mixture of other flowers usually takes away from its consummate beauty. As Browning puts it

"The craftsman thinks to grace the Rose
Plucks a mould flower
For his gold flower,
Uses fine things that efface the Rose."

Let us remember this when arranging our Roses. By over-elaboration and careless admixture of colours it is easy to "efface" their beauty, while by simplicity of treatment and artistic feeling for those forms and colours which lend themselves to grouping we may make charming flower pictures such as no other flower but the Rose can give us.

WHITE LADY.

SOME OF THE NEW ROSES OF 1921

OUR collection of the 1921 new Roses is incomplete—some of the varieties were too highly priced for a slender purse, and the continental specimens were mostly sold out. Thirty-four varieties were tested and, taken all round, they can be said to shew a great improvement on the new Roses of 1920—in fact, some excellent productions have been placed on the market. Let us take them in alphabetical order.

Annie Gregg (H. T., Chaplin Bros.).—A medium grower with large pale pink blooms with deeper pink centres. Of poor shape, however, and it seems a questionable policy to put such "new" varieties on the market at all.

Bessie Chaplin (H. T., Chaplin Bros.).—Quite a superior article: a strong, erect grower, with large bright pink blooms of Caroline Testout type, but a more pointed shape. Although perhaps an exhibitor's Rose, it would be useful also as a

garden variety, where its sweet scent would be especially appreciated.

Coral Cluster (Dwarf Polyantha, R. Murrell).—A unique break in dwarf polyanthas, so far as colour is concerned, being a pretty coral pink. A strong grower with large trusses of blooms, reputed to be a sport of Orleans, but it is firmly established and shews no sign of throwing back.

Duke of Normandy (H. T., Jersey Nurseries).—Very vigorous and upright growths, with good

ROSE SUNSTAR.

FULL AND FRAGRANT, MRS. HORNBY LEWIS.

trusses of blooms. Correctly described in catalogues as a high coloured La France; Disbudded, the blooms would be strong enough for an exhibition box. Origin St. Helena × George Dickson. Well worth a trial.

Earl Haig (H. T., Alex. Dickson and Sons).—A strong grower with large crimson blooms. Although considered a bedding variety, most of the blooms are quite good enough for an exhibition box, as they are full and come a good shape. It mildews slightly, but to its credit it is very sweetly scented and should be grown by exhibitors who also want good, effective beds of bloom in their gardens. A gold medal Rose.

Elizabeth Cullen (H. T., Alex. Dickson and Sons).—Another gold medal Rose. A fine bedding Rose and an improvement on K. of K. A strong grower, giving masses of large semi-double, deep crimson blooms, making a wonderful effect when massed in a bed. Water occasionally in dry weather. My experience is that this strain of Roses resents drought.

Etoile de Feu (Pernetiana, Pernet Ducher).—Medium growth. Yellowish-pink to flame red blooms, globular in shape, but too much like our old friend Louise Catherine Breslau, though more fragrant. Hardly any call for this as a "new" variety.

Ethel James (H. T., S. McGredy and Son).—Good, strong, bushy growth, with single blooms very similar to Isobel, though not such a tall grower, in fact bloom and plant might be described as a refined Isobel. Sweetly scented and an excellent bedding Rose, especially for amateurs who have not already got a bed of Isobel in their gardens. Well deserved the gold medal of the N.R.S.

Ethel Somerset (H. T., Alex. Dickson and Sons).—A good, clean grower of bushy habit, with pink blooms, the colour resembling that of Mme. Abel Chatenay. The blooms should be large enough for exhibition, but are inclined to be a little flat. A profuse bloomer.

Helene Duche (H. T., E. Buatois).—An unwanted variety. Medium growth only, with pale pink blooms of Caroline Testout type, but in no way superior thereto.

Irene Thompson (H. T., S. McGredy and Son).—Medium growth, with clean, erect blooms of orange-yellow colour, well pointed in shape. The dark, glossy foliage is wonderfully effective with the bright coloured and sweet scented blooms. A good bedding variety, to which the gold medal of the N.R.S. has been awarded.

Laxton's Crimson Orleans (Dwarf Polyantha, Laxton Bros.).—A strong grower, in fact so tall that it is almost a misnomer to call it a Dwarf Polyantha. Big trusses of crimson blooms, with foliage similar to Orleans, but it is not quite fixed, some growths throwing back to its original parent. Very free flowering, the blooms continuing through the autumn months.

Mme. Edmond Gillot (H. T., Pernet Ducher).—A moderate grower, with large reddish-yellow, cup-shaped blooms. A garden Rose, hardly a novelty, and no call for it as a "new" variety.

Margaret Horton (H. T., Elisha Hicks).—A good grower with nice clean foliage. Long pointed buds, large well-shaped blooms held erect, deep orange in colour. A good bedding Rose.

Martha Drew (H. T., S. McGredy and Son).—Upright medium growth. Large creamy-white blooms, with light pink centres, resembling in colour Mme. Augustine Guinoisseau. Not in my opinion quite up to the usual high standard of Messrs. McGredy's productions, although it has been well shewn and awarded the gold medal of the N.R.S.

Mary Munro (H. T., J. H. Pemberton).—A very strong grower, with heavy light coral pink

blooms, globular like Caroline Testout. The foliage is excellent.

Minnie Sanders (H. T., Elisha Hicks).—An excellent grower. Straight shoots, with big trusses of bloom. The buds are quite pretty—of Red Letter Day type, but scarlet rather than crimson.

AN ORANGE OPHELIA, ROSE MARGARET HORTON.

Blooms are bright red and do not fade. Very free flowering; it will prove a splendid bedding Rose.

Mrs. Henry Bowles (H. T., Chaplin Bros.).—A good grower, upright in habit, with heavy warm pink blooms, reminding us of the old Koningin Carola. A splendid exhibition variety, it being quite an exception to find a badly formed bloom. One of the best exhibition Roses of the year and well worthy of the gold medal bestowed on it by the N.R.S. judges.

Mrs. Hornby Lewis (H. T., Elisha Hicks).—Strong growth and a good shaped plant. Large, erect blooms, pale yellow, with deeper centres, rather flat in shape. Sweetly scented, but unfortunately not altogether mildew-proof.

Mrs. Oakley Fisher (H. T., B. R. Cant and Sons).—This really is a distinct novelty and as such worthy of a special reward. The plant grows strongly and keeps a good shape. The blooms are single and a rich orange-yellow similar to Lady Hillingdon. It should prove the most effective Rose for dinner table and home decoration since Irish Elegance was put on the market, and bids fair even to outclass that wonderful production. Everyone should grow Mrs. Oakley who loves a real decorative Rose.

Princess Victoria (H. T., S. McGredy and Son).—An excellent grower and very free bloomer. The plant when in bloom is most striking and a bed of them should be a veritable sight for the Gods. The shapely scarlet-crimson blooms shew up brilliantly amid the dark, glossy foliage. A real

gold medal Rose with an extra point for its fragrance. It should quickly prove to be the most popular Rose of the season.

Rev. David R. Williamson (Pernetiana, Pernet Ducher).—Good grower, with heavy trusses of blooms, which rather resemble Lyon, and are coral red, shaded lake. Sweetly scented and a free bloomer.

Rev. F. Page Roberts (H. T., B. R. Cant and Sons).—Strong, upright grower which seems to point to Duchess of Wellington parentage, although the shape of the blooms resembles Lady Plymouth. The blooms are very bright yellow, suitable both for exhibition and garden, and sweetly scented. Another really good new Rose which has justly been awarded the N.R.S. gold medal.

Ruth (H. T., J. H. Pemberton).—From its habit of growth, blooms, foliage and thorns this should rather be described as a Pernetiana than a H. T. Mr. Pemberton seems to have struck a new type here which should have a good future. It is a strong grower. The blooms are orange-carmine, but lighter than Miriam. Good foliage and sweetly scented.

Sammy (Hybrid Musk, J. H. Pemberton).—A cluster Rose of Grüss an Teplitz type, which it resembles closely, except that it is almost scentless. Very strong grower, but unfortunately subject to mildew.

Soyecourt (H. T., Jersey Nurseries).—Parentage is General McArthur × G. C. Waud. The growth resembles McArthur, being very erect, but the blooms are smaller with just a tint of G. C. Waud

colouring. A pretty, sweet scented buttonhole Rose.

Souvenir de Georges Pernet (Pernetiana, J. Pernet Ducher).—A very strong and erect grower of Mine. Edouard Herriot blood. Large, rather flat blooms, deeper coloured than Lyon. A free bloomer, but scentless. A fine addition to the Pernetiana class, to which the gold medal of Bagatelle was justly awarded after the Rose had been tested in the Paris Rose Garden over a period of two years.

Souvenir de Mme. Boulet (H. T., J. Pernet Ducher).—Strong branching growth and blooms carried well and erect. Dark yellow blooms resembling Mme. Ravary, but heavier and of better shape. The blooms last a long time in flower when the weather keeps fine, but they lose colour somewhat in wet. In the autumn the blooms are very similar to Lady Hillingdon. It should prove strong enough for exhibition.

Sunstar (H. T., Alex. Dickson and Sons).—Excellent bushy growth, with large trusses of blooms. A most effective bedding Rose, with a fiery combination of colour described as orange splashed with red. Quite an unique variety, but well remembered by visitors to the big rose shows, where it has been so often staged in baskets and nearly always secured the premier awards.

Toison d'Or (H. T., J. Pernet Ducher).—A good grower with nice straight shoots. Bright apricot yellow blooms shaded orange, but rather flat in shape. A very fragrant bedding Rose.

Una Wallace (H. T., S. McGredy and Son).—Vigorous upright growth, with blooms carried erect on long stems. Cherry rose colour, good foliage and free blooming. Although a gold medal Rose we should like to try it another season before finally pronouncing on its merits.

Waltham Flame (H. T., Chaplin Bros.).—Very vigorous grower with large trusses of bloom. The buds are pretty, blooms are semi-single and coppery salmon colour. A garden Rose, but unfortunately it seems to be subject to mildew.

Yvonne (Wichuraiana, Frank Cant and Co.).—The only climbing Rose of the season. Fairly strong, good glossy foliage and big trusses of light pink blooms, with yellowish base. Very fragrant. D deservedly awarded the gold medal of the N.R.S.

Yves Druhen (H. T., E. Buatois).—Parentage General McArthur × Château de Clos Vougeot. It has the growth of the former with blooms of the latter, rather a good combination. The half open buds are very pretty and the full blooms would appeal to those who love dark red velvety Roses.

Such are our first impressions of some of the new Roses of 1921, most of which are good, and others will doubtless improve upon acquaintance.

It would be difficult to select one to crown as the best new Rose of the year, but fairly easy to

select the best of each type or classification. Bedding Roses are perhaps the most popular and of these Princess Victoria must undoubtedly stand pre-eminent. Elizabeth Callen, Minnie Saunders and Souvenir de Georges Pernet are all second best, and well worth considering for new beds.

The singles we put in another category. Two of them would tie for first place, namely Mrs. Oakley Fisher and Ethel James.

Yellow Roses seem to be all in the fashion nowadays, and there are two new varieties for all round purposes—decorative and exhibition, viz., Rev. F. Page Roberts and Souvenir de Madame Boulet. Both should be grown.

Of high standard exhibition Roses, first awards will undoubtedly go to Mrs. Henry Bowles for a pink, and Earl Haig for a red.

The best new Dwarf Polyantha of the season is Coral Cluster, and the only climbing Rose Yvonne.

Finally, from the novelty point of view Sunstar stands first and will attract attention in every garden, while Ruth should not be passed without a reference.

I shall hope to complete the full catalogue of 1921 new Roses next season with the addition of Messrs. Hugh Dickson's, Bees', Wm. Paul's and others which were lacking this year, and thereby shall be able to pronounce better judgments on the whole year's productions. H. L. WETTERN.

PLANTING ROSE TREES

How to make the best use of various garden soils.

THE principal questions that immediately beset the novice in Rose growing are very much the same as in other gardening operations—the When and the How. At the moment varieties are no real worry: the beginner usually has already prepared a long list—far too long for his garden, of course—of varieties it is hoped to grow. This is soon modified. The nature of the soil does not at the moment seem greatly to matter, and in any case most gardeners have to take their garden soil pretty much as they find it. Yet on mature consideration the character of the soil is an important matter.

Roses are, or should be, of the nature of permanent occupants of the garden, and it is most important to give them as good a start in their new lives as possible. If mistakes are made with any of the plants in the hardy flower border, it is very disappointing, but not really serious. It can usually be remedied fairly easily, but when about to plant Roses at least as much care in preparation and selection should be taken as for fruit trees.

The ideal Rose soil is quite a heavy loam, if it approximates to clay so much the better. It is in gardens on such soils that the best exhibition Roses are grown. The admixture of clay to light soils, in order to make them more suitable for growing Hybrid Perpetuals and the larger Hybrid Teas, has been recommended, but the present writer, having tried the experiment years ago, has come to the definite conclusion that it is a decided mistake. There are great mechanical difficulties to be overcome, and although a great deal of labour was expended, the Roses objected, and the experiment was realised to be another of life's disappointed hopes.

In Rose growing one must bow to the inevitable to a great extent, and confine one's attention to the types of Roses that will succeed in the soil being dealt with. There are Roses suitable for all garden soils ranging from the very heaviest down to almost pure sand. Although the purpose of this article is not to give lists of suitable Roses

for various purposes, soils and situations, it may usefully be stated that most of the Wichuraiana and the Dwarf Polyanthas will do well in the very poorest of soils, while no one should hesitate to plant the beautiful Hybrid Tea varieties in soil of average texture. The owner of a garden in which the soil is moderately light, but good, and in not too cold a district is one of the enviable persons who could grow the wonderfully beautiful and deliciously fragrant Tea Roses to perfection. These most fascinating of all Roses are sadly neglected nowadays, yet in any of the few public gardens where they are grown they attract more attention than any other type. Although they thrive only indifferently well at Kew, the beds devoted to the delicately fashioned Tea Roses compel an immense amount of admiration during their long season of flowering. In that most successful rose garden at Chalkwell Park, Westcliff-on-Sea, there used to be, and no doubt still are, Tea Roses that delight thousands of visitors through the summers and autumns. The Teas are considered by some to be too tender for everyday use, but if on the approach of winter some soil is drawn up around the stems, the plants will survive very hard frosts. The branches are often killed, but then the next season's shoots are all the stronger for Nature's pruning.

The best position for Roses is the best position in the garden. Roses are not hole-and-corner plants; they demand and deserve the lightest, airiest and most sheltered place that can be given. Although the wild Rose is often found in natural woodlands, it is on the very outskirts of the wood that it thrives, and it flowers best on the sunniest side.

Although one must to great extent take the garden soil as one finds it, yet a deal may be done to improve it when it is not quite so suitable as may be wished. If the light soil can have the addition of a few loads of pasture loam, well chopped up and thoroughly mixed with it, the extra vigour of the Roses and the higher quality of the blooms will amply repay for the work. The best manure

is well decayed farmyard manure, and instead of placing this as a layer beneath the top spit of soil, it is of much greater value when thoroughly incorporated with it. Contrary to the idea which seems to be far too prevalent, the Rose is not a gross feeder, and layers of strong animal manure will do more harm than good. Where, as so often happens, one must literally deal with the soil as one finds it and it is not possible to add better soil, recourse may be had to chemical manures in order to provide sufficient plant food. Phosphates are most essential to the Rose's well being, and the cheapest artificial form is as basic slag. For a long time it was believed that basic slag was suited only to the heavy soils; whereas, if it is dug in sufficiently early, it is equally valuable on light soils, even when used for a crop of only annual duration, while its comparatively slow action renders it admirable for Roses. When preparing the beds or borders, basic slag may be dug in at the rate of 1 lb. per square yard on poor soils and at about half this quantity for moderate soils.

The value and necessity of lime has yet to be learnt in very many gardens. Great numbers of garden soils are deficient in lime, and unless this is present full value cannot be obtained from any manure that is used. At least ½ lb. of lime per square yard should be spread on the soil for Roses and be dug in.

Except in very heavy soils in cold districts, the greatest success in Rose planting is obtained when the work is done not later than the end of November. This autumn planting allows time for the bushes to become established before the next growing season commences, and root action is always better at this season, while the soil is still warm, than later on. If for various reasons the work cannot be done towards the end of October or during November, it can be carried on later whenever the weather is suitable. It should on no account be proceeded with when the soil is wet and sticky or during frosty weather. If the Roses arrive at such times it is far better to lay them in temporarily or even to place the bundles, still packed, in a frost-proof shed until conditions improve.

As has already been indicated, no trouble should be considered too great to ensure that the Roses are well and truly planted. When planting in a very heavy soil it is well worth while to have some prepared soil if only to sprinkle around the roots. Old potting soil will do admirably for the purpose and by its aid the roots can be properly covered and made quite firm. If the roots are at all dry, they should be dipped in water. All broken roots should be cut cleanly in an upward direction, and they should be spread out evenly and, even though the fingers are used, the soil must be placed well around each root. This may sound, and be, a tedious business, but attention to such detail is well worth while. The correct depth to plant can be seen by the soil mark on the stems, but if the soil is very light it is well to plant the bushes a couple of inches deeper than they were in the nursery.

The planting should be done quite firmly in all cases and in all soils. When planting early it is well to leave the surface of the soil around each Rose somewhat saucer-shaped in order to facilitate watering should this be necessary, but at the beginning of December this depression must be filled up, and it is usually wise more than to fill it and to have a little mound of soil around the stems of the Roses. At this season pruning is neither necessary nor advisable, though any unduly long shoots may be shortened in order that the bushes may not be blown about by winds. When planting late in spring, however, it is best to prune the Roses at planting-time. A. C. B.

CORRESPONDENCE

THE AZURE SAGE.

I WAS pleased to see a reference in *THE GARDEN* (page 526) to that fine plant, *Perovskia atriplicifolia*, and to hear that it occupies a place of importance in "The Master's" garden at Gravetye. The surprising thing about *P. atriplicifolia* is that one so seldom sees it, for it appears to be hardy enough for all but our bleakest districts and does not ask any more than ordinary well drained loam in a sunny spot. Even in places where the winters are severe enough to injure the growths the root will generally survive with a little protection and break away in spring like a hardy *Fuchsia*.

P. atriplicifolia belongs to the Sages and it is a sub-shrubby plant of some 3ft. high, the stems and leaves being almost white. The flowers are borne at the ends of the new growths in a spike several inches long and their vivid violet-blue in a woolly setting of white gives a most striking effect.

be as effective as a mass giving a range of shades that harmonise with Pink Pearl. Who, for instance, would prefer a bank of wild Dog Roses all exactly the same shade, or a meadow in Upper Teesdale, mauve with *Primula farinosa*, that did not show a subtle difference in tone between plant and plant on closer inspection! Perhaps in five years' time I would make many alterations after having had more experience with such things as *Eucryphia pinnatifolia*, *Rosa Moyesii*, etc., and if I could grow *Rhododendron campylocarpum* as I saw it at Edinburgh this year, and *Magnolia Soulangeana* and *Arbutus Unedo rubra* as they grow at Kew, they certainly would have to be included.—R. B. C.

MAY I add the names of another "twelve best shrubs" that flourish in my little garden at Dawlish: *Genista Dallimorei*, *Tricuspidaria lanceolata*, *Veronica Hulkeana*, *Chimonanthus fragrans*, *Berberis Thunbergii*, *Daphne indica*, *Fabiana*

question as to whether the Rose is full, thin or only semi-double is one of the most important points. If you could effect a change as regards this, I for one should be very grateful.—N. ROYDS.

[The point raised is an important one, but, of course, form in a Rose implies something more than a question of mere "fulness" or "thinness."—Ed.]

IRIS UNGUICULARIS SEEDING.

IRIS unguicularis (*stylosa*) flowered well here last winter, thanks to the hot summer of 1921. I brought the roots from Algeria some years ago, and though they produced a number of flowers at first, for several years none had appeared. I felt sure that the lack of flowers was caused by the roots not being sufficiently ripened, and last year's experience seems to prove this to be the case. In East Yorkshire, autumn is usually damp and chilly, so that plants requiring late autumn sunshine do not do well here. Last year the flowers on this Iris began to appear in November—I gathered some before I left for Italy in the middle of that month—and they were in full flower when I returned in February, and lasted till April. I have been interested in finding several ripe seed pods, and hope to succeed in raising some young plants, having already sown two or three pots, while other seed is still drying in the sun.—RUTH BICKERSTETH, *Cottingham, East Yorks.*

A LATE-FLOWERING AZALEA.

I HAVE read with interest the note on a late-flowering Azalea (*Azalea occidentalis*), in the August 19, 1922, issue of *THE GARDEN*, page 420. Thinking that you might be interested in seeing a photograph of the plant in its native habitat, I am sending a print to you herewith. This plant was photographed by me at Eureka, California. The gentleman in the photograph is the late Mr. C. W. Ward, who for many years was one of our leading Carnation growers and also the proprietor of a nursery at Queens, Long Island, as well as Eureka, California.—PETER BISSET, *Plant Introducer in Charge of Experimenters' Service, Bureau of Plant Industry, Washington.*

THE ELSCHOLTZIA.

FOR several years a plant of *Elscholtzia Stauntonii* at Castleford, Chepstow, has attracted a good deal of attention from visitors during the months of August and September, when it is usually in bloom. It is a semi-shrubby plant, and forms a bush about 4ft. across and 2ft. high when it is in flower, but during the winter months the growths die back to the extent of 1ft. or 1½ins. In the spring it begins to grow again, and pushes up leafy shoots, which eventually bear large spikes of carmine-pink flowers. Individually these are small and crowded, but a well grown plant is quite effective and worthy of a place near the front of a shrubbery or where it will be fully exposed to the sun. Plants in shady positions are not nearly so good, the growths being too weak to support the flower-spikes. It is quite hardy, and was introduced from China in 1900. This plant belongs to the Natural Order Labiate, and the leaves when crushed in the hand have a mint-like odour. It may be propagated by cuttings made from the young shoots, and these soon form roots if placed in a cold frame or cool greenhouse.—F. W. B.

CUP ANOMALIES OF THE ROYAL HORTICULTURAL SOCIETY.

ON page 533 of your issue of October 21, Mr. Elisha J. Hicks raises a just query as to who won the Wigan Cup. This brought to my mind the position of the East Anglian Horticultural Club in

RHODODENDRON (AZALEA) OCCIDENTALE IN ITS HOMELAND.

These flower shoots are excellent for cutting and the blossoming season extends from the end of summer well into autumn. The whole plant has the odour of Sage.—N. W.

THE TWELVE BEST SHRUBS.

REFERRING to your correspondent's letter on page 507, my list would include *Rhododendron Nobleanum*, *Hamamelis mollis*, *Ribes sanguineum*, *Prunus triloba* fl. pl., *Rhododendron racemosum*, *Berberis Darwinii*, *Berberis stenophylla*, a good Lilac, *Rhododendron Pink Pearl*, *Robinia hispida*, *Escallonia langleyensis*, *Cistus laurifolius*. This list is based on twenty years experience in a North-umberland garden situated on the side of a hill about 500ft. above sea level. The names are given more or less in the order of flowering, and *Rhododendron Nobleanum* and *Hamamelis mollis* are only included on account of their early blooming. *Robinia hispida* is perhaps more of a tree than a shrub, but in an exposed situation is only suitable when grown as a shrub. Although these are all suitable for massing, it does not follow that a mass of such as *Rhododendron Pink Pearl* would

imbricata, *Diplacis glutinosus coccineus*, *Magnolia nigra* and *stellata*, *Leptospermum Nicholli*, Heaths (*Ericas mediterranea* and *Veitchiana*), *Melianthus*—VIOLETT C. BENTINCK.

I HAVE read with much interest the lists of twelve best shrubs. Here, on stiff loam with lime, the best seem to be: White Mezereon, Double Peach, *Prunus Pissardi*, Crab John Downie (equally beautiful and useful for fruit), *Forsythia suspensa*, *Berberis stenophylla*, Lilac Mme. Lemoine, *Choisya ternata* (which blooms twice), *Spiraea japonica*, *Crataegus Pyracantha*, *Arbutus Unedo*, *Viburnum Tinus*. The evergreens are decorative at all times of year. I hope to try *Viburnum Carlesii* and *Eucryphia pinnatifolia* this autumn, but am told the latter dislikes lime.—E. HUNTINGFIELD.

THE FORM OF ROSES.

IT is much to be regretted that in notes on new Roses the form is so often omitted. Even in the National Rose Society's Official Catalogue it is not mentioned, and yet to many of us the

respect of the challenge cup for hardy fruits—open to affiliated societies. In 1920 the East Anglian Club won premier position and I think brought the cup home, to the pride of its members. In 1921 they secured the coveted position again out of four entrants, but neither had the cup nor any compensating award. This year they did not think it worth trying for again, and perhaps other societies were of the same opinion, for there was no entry in the class. What I should like to know is, where is the cup and who is designated the holder?—HERBERT PERRY, *Norwich*.

[No doubt, as there was no entry this year, the R.H.S. have retained possession of the cup and will offer it again next season. The rule that certain cups must not be won two years in succession by the same exhibitor is, in our view, thoroughly bad, but the cups are doubtless disposed of according to the wishes of the donors and there is an old adage about "paying the piper and calling the tune."—ED.]

AUTUMN FLOWERING OF BEARDED IRISES.

IT is not unusual for some varieties of Iris to flower again in the autumn. Peter the Great has been in flower since September 20, and will

full beauty. It is a vigorous plant, and is quite hardy in most parts of the country. No doubt it is the finest of the Abelias which are suitable for outdoor cultivation. It is readily increased from cuttings, and they will form roots at almost any time of the year.—B

A GROUP OF HYDRANGEAS

I ENCLOSE a photograph of a group of the common Hydrangea, *H. hortensis*, growing in these gardens. They always flower well, but I have never seen them flowering so freely as this year. The unusual wealth of blossom may probably be accounted for by the thorough ripening of the wood caused by the heat and drought of last year. The two tall middle plants have been in their present position for about twenty-five years; they are between 8ft. and 9ft. in height and nearly as much through. The end plants were put in about ten years ago. They are protected on the north side by the fern house shewn in the picture, on the east by a large Yew, but are fully exposed to the south and south-west. They receive no attention beyond cutting off the dead flowers and shortening back any growth that may have encroached too far over the Rose bed in front. They get nothing in the way of

Mimus aurantiacus. There are several forms or hybrids of *D. glutinosus*, and they vary in colour from shades of red to yellow. No doubt this plant would be destroyed if the winter was a severe one, but it is well worth the trouble to replant it in the more favoured parts of the country. It is readily increased from cuttings, which will root at any time during the spring and summer months. A few plants could be accommodated in the cool greenhouse, to take the place of any that are destroyed by frosts. Anyone who has seen a healthy and vigorous plant outside with its wealth of bloom spread over a long period will be inclined to despise it as a pot specimen with its restricted root run and somewhat starved appearance.—T. W. B.

THE CULTURE OF THE SILVER BERRY.

THAT beautiful species, *Eleagnus argentea* (not to be confused with *Shepherdia argentea*) is one of the most silvery bushes that it is possible to conceive and the tubular yellow daphne-like flowers are as pretty as they are fragrant. But although I have had this species sent over from Canada and also got plants from an Irish nursery, it does not seem to be happy in our hands. Can any reader tell me what it needs? On the prairie of Saskatchewan it is mainly confined to the higher levels, or knolls, where the soil is comparatively dry and deficient in humus and there it grows in masses, spreading by means of suckers, which, latter, I am told are not so apparent in cultivation. The farmers over there call it "Wolf Willow," but it is also known as "Silver Berry," since the fruits, in common with the twigs and leaves, appear as if dipped in aluminium paint.—A. T. JOHNSON.

FOR A SUNNY CORNER.

THAT little Daisy-like thing, *Erigeron mucronatus*, is surely the most cheerful Southerner that ever found place in our gardens. The weather has so little effect upon it that a group of plants have flowered no less abundantly during this cold and wet season than they did during the torrid heat of last summer. Normally, *E. mucronatus* (more properly, *Vittadenia australis*), makes a rounded mass of thin and elegant stems some gins. high and a foot or more in diameter, and throughout summer—from the end of May to the first frosts of autumn—it bears a profusion of pretty Daisies which open a good deep pink and die-off white, so that flowers in both colours and every intermediate shade are open at the same time. No plant that I can call to mind yields such a constellation of blossoms for so long a period and, what is more, *E. mucronatus* never seems to grow weary of this "mass production." The blooms which pass away leave no unsightly remnants behind them, there is no shabby period, no "running to seed." The plant is as clean and bright and full of life and colour at the end of October as it is on Midsummer Day. All that this amazing little plant asks is a free, warm, gritty soil and "a place in the sun," and there it will freely propagate itself by seed.—CAMBERG.

ARALIA CHINENSIS.

THIS Chinese shrub with its sub-tropical look never fails to arrest attention. It is not much in evidence in gardens, more especially north of the Tweed, it not being regarded—and that rightly—as quite hardy. The ideal site for it is a well drained, sheltered spot. It was therefore a pleasant surprise to me when on a visit to Perth in September to find quite a good specimen of it in a villa garden at a high altitude and in an exposed situation in Craigieknowe, a suburb of the Fair City. Doubtless the perfect drainage was an important factor in its welfare.—C. C.

SOME FINE "CHANGEABLE GARDENERS."

continue for some time yet it not cut by frost. The flower-stems are not so high as those produced in spring and the flowers a little smaller, but there are a goodly number and the effect is quite pleasing. The following have also flowered, but not so well: *Crimson King*, *Florentina alba*, *Louise* and *atropurpurea*. I have noticed that this autumn blooming habit does not appear to prejudice free blooming in spring.—G. N. B., *Maidstone*.

A LATE-FLOWERING SHRUB.

FLOWERING shrubs are none too plentiful during the months of September and October, hence the reason for calling attention to that delightful plant *Abelia grandiflora*, which is still a mass of its pretty, almost pure white flowers. I have had the same plant under the names of *A. rupestris* and *A. chinensis*, but no doubt the above is the correct name, and it is stated to be a hybrid between *A. chinensis* and *A. uniflora*. It is evergreen and from 4ft. to 5ft. high, and the slender, arching growths are covered with bloom. The leaves are a shining dark green, and the general habit of the plant makes it desirable for an isolated position where it can develop its

manure but a little soil is thrown over the dead leaves that drift under them during winter. They generally commence flowering in July, but, like other things on this East Coast, were very late this season. I noticed the first open flower of the *Belladonna Lily* on October 9. Last year the plants were in their full beauty by the end of August. I might say that we are situated about a quarter of a mile from the coast, with no protection whatever between us and the sea.—H. REYNOLDS, *Scrabby Hall Gardens, Great Yarmouth*.

DIPLACUS GLUTINOSUS.

IN most parts of the country this pretty shrubby plant is cultivated under glass, but in mild localities it is well adapted for a warm corner with a south aspect. A plant at Castleford, Cheshire, has been blooming freely throughout the summer—in fact, so long as conditions are favourable to growth the shoots continue to produce flowers. It is a native of California, and will attain a height of 5ft. The flowers are salmon colour, and greatly resemble those of *Musk*. This plant is also known as *Mimus glutinosus*, and it was figured in the *Botanical Magazine* as

DEUTZIAS FOR THE COLD GREENHOUSE

THOUGH perfectly hardy shrubs in the ordinary sense of the word, many of the Deutzias are worth protecting, particularly the varieties or hybrids of *D. gracilis*, which commence to unfold their leaves and flower rather early in the season. Spring frosts, although they seldom entirely destroy the beauty of the bushes, frequently considerably impair it. Certainly, if allowed to develop under glass, protected from winds and rains and sudden rises and falls of temperature, the blossoms are usually seen to much greater advantage. Under glass also, even without artificial heat, the flowers open in advance of those outside.

The cultivation of the bushes in large pots or tubs presents no difficulty. This is preferable to

D. GRACILIS is pure white; var. *erecta*, has upright branches wreathed in snow-white flowers; var. *fastuosa*, long inflorescences with twenty to twenty-five flowers, milk white; and var. *rosea*, pink-tinted blossoms.

D. CRENATA *eburnea* has light and graceful clusters of white flowers in profusion; var. *erecta*, is more upright in habit, producing pyramidal clusters of large milk-white flowers; var. *formosa* is one of the best double-flowered sorts, pure white; var. *latiflora* has large white flowers 1 in. to 1½ in. across and fifteen to twenty together in upright panicles; when var. *magnifica* was shown at one of the Royal Horticultural Society's meetings this profuse flowering pure white variety was given an award of merit; var. *staphyleoides* is one of the largest white-flowered Deutzias.

D. BISCOLOR *elegantissima* has carmine buds opening to dainty pink blossoms; var. *excellens*

has been called the crataegus-flowered Deutzia, one large flat corymbs of blossoms closely resembling those of the Hawthorn; var. *fasciculata* has arching branches of pale pink blossoms. The fine *D. Wilsoni*, pure white, is closely related.

After flowering the aim should be to obtain as much new growth as possible, as the wood now formed will produce next season's blossoms. Remove as much of the old flowering wood as possible when the flowers shatter, seeing that some, at least, of the oldest branches are cut out to the base each year. Copious supplies of water and liquid manure may be given when growth is active. When placed outside in June a little shelter from the brilliant mid-day sun may be worth while at first, but by August, when growth should be complete, they should be moved to fully exposed positions in order thoroughly to ripen the wood. A. O.

THE TOWN GARDEN

How to make and maintain it satisfactorily

A NEW interest and a changed outlook on London life is surely dawning in the advent of a *bona-fide* garden of one's own into which it is but a step from the house through some connecting doorway. Even if the available space be of so small an area as 40ft. by 20ft. or even less, this desirable possession can be quite successfully acquired, especially if the walls on either side are not too high.

First, it is well carefully to take down any creepers that may be already on the walls and to erect a wooden trellis painted green, taking care, also, to run wire netting all round the outside walls and reaching quite 2ft. above the top of them in order to exclude cats, after which the creepers should be carefully trained to the trellis and netting, and at once one gets a pleasant background for the garden proper.

There is no doubt that a stone-paved court with spaces between the stones in which to grow rock plants, with shaped flower-beds next the walls, is far the most effective, practical and picturesque way of treating the London garden.

It is a mistake to consider that there are all-pervading smuts, that one cannot sit in a "London dress" on the garden seats without getting the benefit of them; it is a mistake to think that, whatever one plants, it will stay unwillingly for a few days and then die off; it is a still greater mistake not to make an intelligent study of what will flourish in London in the aspect and the soil it has to be planted in. The "self-faced" paving now in vogue is admirably suited to these small spaces, and every flower and every leaf growing near it cannot fail to "tell." The initial expense of laying it down is well worth while, for it makes it most easy to be one's own gardener with very little extra help once the garden is arranged. I can only speak by experience, and I think many will be encouraged to acquire that precious possession—one's own garden in the heart of a great city.

We cannot easily forget arriving just as our house was being finished, its exterior and interior fresh and charming, when behold! our eyes rested on a scene of perfect desolation without. Grimy walls, grimy gravel, the dreary remains of aged flower-beds, old boxes, even concrete slabs—40ft. or so of ugliness.

We felt this terrible state of things must not continue, and forthwith set to work to call in aid as to planning, paving and trellising, and for this I strongly recommend expert advice, especially for the inexperienced. One saves time and money

thereby. We began operations in the spring of this year, before Nature had covered up ugly walls with the leaves of Vines and creepers which, indeed, were mercifully there, and at a season when no garden looks its best, especially if there has been the tramp of many feet over it and a litter of tools cast in every direction! After this depressing picture let me describe what we found on another return in early autumn after only a few months' planning and watching for results, for we left the garden for many weeks with only an occasional hour's attention from a visiting gardener.

The Fig tree has now mellowed into gold and green, its outstretched "hands" or leaves will not long be uplifted but cast down. It is still pleasant, however, to sit under the branches at the end of the garden, to hear the pigeons cooing and a neighbour's bird singing, and to see the bunches of Grapes ripening on our Vines. The great Peony-flowered Dahlias are over 6ft. high with blooms measuring half a yard in circumference, mauve, scarlet, white and wine colour—a gay company! We wondered when they were planted in early summer whether they would ever grow up! Here the bees have come, how and whence I know not, and clustered busily where the Dahlia has opened its heart. The mauve stars of the Michaelmas Daisies are spangling the garden, and golden and Bronze Chrysanthemums are aglow in the sun's rays. The white and purple Thymes have finished flowering, but they grow apace, and are now like green mats flung on the paving stones. The Violas, too, have done their flowering, but are making good with further green shoots and filling up corners, as are the double pink and white Daisies, which have sown themselves in the crevices of the stones all about the garden. Watch must be kept, of course, for caterpillars.

The Jasmine, which was a small plant put in early in the summer, has now climbed high over the fence, and a little Rose tree is covered with late bloom. Stone vases and green tubs stand about here and there, two of them occupied by frilly petticoated carmine and white Fuchsias which have flowered all summer long. Now let me say a word about watering. However much it rains, always see that plants in tubs and such like do not get neglected, for no rain will penetrate under them.

In talking of autumn effects in our little garden, I like to point out that it is not only bedding-out and easily removed plants that flourish—those

THE PURE WHITE DEUTZIA WILSONI.

planting out in the borders, as it is not only better for the health of the plants to be outside from June to January, but leaves the house vacant for other plants.

A fibrous loamy soil is the best for Deutzias, with the addition of some old decayed manure, leaf-mould and coarse grit. Repotting, or tubbing, of the bushes should not be necessary for three or four years, if a top-dressing of rich soil, or half loam and half rotten manure, be given annually in January, after removing some of the surface soil. The smaller plants can be readily grown in 6in. and 7in. pots.

Increase by division, layering and cuttings provides easy means of propagation. Cuttings made of the half-ripe shoots about midsummer root readily in a close frame or under bell glasses.

A selection of the best for flowering in the cold greenhouse follows.

that are with us, as it were, on a visit—but that it is those that are *here to stay* that win our special affections, the climbers and such herbaceous things as are suited to our conditions.

Not the least charm of all is that real atmosphere of a garden one can get even in so small a space as ours. Where else can we go out into the open air, hatless and gloveless and undisturbed! Think of the blessing of this to a busy city man, a Member of Parliament, or to anyone pursued by conventionalities and obliged continually to acknowledge the greetings inseparable from public life, or, again, to the tired woman-worker whose avocation condemns her to stuffy studio or class-room.

Never do we return to London in the autumn without a pang of regret at turning our backs upon river, mountain, moor and lake and all the wonderful beauties of Nature at her loveliest—yet am I bound to say that this year grey skies and soaking countryside and the breaking down of a motor miles from anywhere took the glamour from the scenery. Next day, however, the bright sunbine, the gay colour in the brilliant flowers, the quickly dried paving stones and inviting garden seats made us feel that we can indeed "get almost everything in London."

I remember years ago being asked by my host at luncheon, "What do you think of my garden?" (this a small space behind his London house). "I have planted a Fig tree!" There was, it is true, one occupant of the said "garden," a drooping Fig tree thoroughly resenting its transplantation. Those were early days for London gardens, but I felt so disappointed at the efforts of a really distinguished naturalist that I answered, I am afraid, in a rather uncomplimentary tone, "I think it reminds me of what is said in the collect, 'By reason of the frailty of our nature we cannot always stand upright.'"

Do not put too severe a strain upon your tree or plant, and always transplant it at the right time, if possible in early spring in London rather than late autumn. Get good specimens, do not rely on cuttings or seeds (experiment with them if you like!). Do not be content with "bedding-out," for the charm of such a garden is much in its setting, that is, in the things that really *grow* and flourish. Never expect plants to flourish under the drip of trees. Here is where pavement comes in, and the effect of sunlight on it, flickering through the trees, is very attractive. There is always something to do when one walks round. One can cut off all dead flowers, especially from the *Violas*. They will then remain in flower very much longer, and they flourish amazingly with us, as do *Pentstemons* also, and *Catmint* London Pride from its name association should find a place, and many other *Saxifrages* too. Many plants that have not spongy leaves and do not hold the raindrops prosper. Even the most unlearned amateur may hope for a gorgeous display of *Tulips* and other bulbs in spring if they plant betimes in autumn.

In the depth of the winter also it is pleasant to look out on formal clipped shrubs, some of them in stone vases, and perhaps a lead figure placed attractively or a sundial. In our Fig tree hangs a green bird-box for tit-bits to be served on cold winter days when natural food is scarce.

To a small house what an addition it is to have, as it were, one large room with the heavens for ceiling, open air for refreshment, and numberless flowers for one's delight! Instinctively one walks out after luncheon or dinner, when the coffee appears on the green table under the tree, a nice country interlude in the day.

Across the road the earliest greenery is to be seen in the gardens of Cadogan Place, so we hope to respond with bright echoes of purple and white *Aubrietia* and *Arabis*.

HILDA HAKING.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Rhubarb.—As an article of food during the spring months Rhubarb is extremely valuable. It can be well grown without a too frequent disturbance on a deep and somewhat sandy loam. Where it is freely used it is a good plan to deal with a portion of the roots every three or four years, and to have the ground in good heart for spring planting, it should be thoroughly dug during the winter and have plenty of manure worked in as the work proceeds. It will be an advantage to have the Rhubarb plot marked off into sections so that newly planted roots and those intended for forcing purposes may be treated accordingly. From now onwards the roots will easily respond to growth provided they are lifted and left on the ground for a week before taking them into a Mushroom-house or warm cellar. Wherever they are accommodated plenty of old leaf-soil should be placed round them and the roots kept uniformly moist. Failing any inside accommodation for early Rhubarb, some deep boxes or pots should be placed over a few roots outside and then be completely covered up with leaves and straw litter to a depth of about 3ft. This method has the great advantage of not causing any waste of roots, as they soon recover to their normal strength after forcing in this manner.

The Flower Garden.

The Torch Lily, or Flame Flower, greatly appreciated last season's warmth, which ripened up the crowns so well, and the result is that in many places this season, although the weather has been most unsettled, the plants have done splendidly. It is not a happy plant for a mixed border, but should be boldly grouped in front of a shrubbery or near a streamside walk, where, perchance, a group of Grasses or other autumn feature may give its stateliness and rich colourings even greater dignity. Where owing to a cold soil there has been a loss of plants during the winter, it would be helpful when severe weather approaches to tie all the foliage up to a stake and to interlace plenty of dry bracken fern, covering the root stools with it at the same time.

The Rockery.—Alpines of a hairy leaf nature liable to suffer from dampness should now be protected by having sheets of glass or horn placed over them and the same securely fastened so that the wind cannot displace them. Any alterations either in the way of additions or remaking are best carried out during autumn and winter as opportunity offers. Keep the undisturbed part of the rockery free from weeds and falling leaves, and give the soil a light pricking over if it has become soured.

Tub Plants, such as *Agapanthus*, *Hydrangea*, *Bay*, etc., which have occupied positions out of doors during the summer should now be got into winter quarters, such as a frost-proof shed or a cold house. The interlacing of boughs of spruce or bracken fern is of great help in wintering shrubs safely, and it should be remembered that dampness is often a greater enemy than frost for many resting plants and roots.

The Hardy Fruit Garden.

Crab Apples.—Do not overlook the planting of these very useful and exceedingly handsome fruits. The spring beauty of the trees when in flower is quite equal to many of the so-called choice shrubs, and in many cases this is followed in autumn by brilliantly coloured fruits, giving them a splendid appearance when well placed in a shrubbery or in suitable positions in the pleasure grounds. It is, perhaps, hardly necessary to touch upon the excellent properties of the fruits for making jellies, etc.

Damsons.—The wonderful crop of these fruits in most districts this season only tends once again to enhance, if such is necessary, their great value as a culinary and preserve commodity. Another great point in their favour is their lateness in coming to maturity, thus prolonging the stone fruit season by several weeks. On account of their hardiness Damsons may be safely, and with advantage to other fruit trees, planted as guard trees, that is, placed on the coldest side of the fruit plantation. In making a selection of varieties the more recently introduced variety known as Merryweather should certainly be included.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

General Work.—During inclement weather advantage may be taken to look over Potatoes that are stored in cellars or sheds, removing all shewing signs of decay. Where seed was not secured at the lifting period, opportunity may now be taken to lay aside the necessary quantity, placing in shallow boxes and storing in an airy frost-proof shed. See that the varieties are properly labelled and thus save confusion when planting-time comes round.

Turnips.—Roots of the Golden Ball variety should now be lifted and stored, as they become overgrown and stringy if allowed to remain longer in the ground. Store in an open shed and cover with straw, when they will be found to remain fresh and crisp for a considerable period.

Autumn Giant Cauliflowers.—These popular Cauliflowers are often in good usable condition well into November, provided no very severe frosts have occurred. To save the curd from being unduly discoloured a careful survey should be made of the plants and a few leaves broken over the flowers. If well placed these also ward off heavy rains. Where the plants are turning in quickly, as they often do during a mild spell, a number may be uprooted and hung up by the roots in a cool shed, where they will be found to keep in serviceable condition for several weeks.

The Hardy Fruit Garden.

Planting Fruit Trees.—Early planting is to be commended, as the trees readily push out a few young roots at this time which allow the trees to make a more generous start in the spring. When the ground and weather conditions prove favourable, no time should be lost immediately the young trees come to hand in having them transferred to their permanent quarters. Should the roots have become dry on the journey, give a thorough soaking before planting. Spread the roots out evenly before covering in, and should the natural soil be cold or of a clayey nature, add a goodly dressing of light fibrous turf. For stone fruit the addition of some lime rubbish will prove beneficial on ground where lime is naturally deficient. Cut away all damaged or broken roots and make standard trees firm by staking. The latter operation is best done immediately after planting is finished.

Raspberries.—Where it is proposed to make new plantations or replace unfruitful or worn-out canes the ground should be well prepared beforehand. As Raspberries usually occupy the same position for a number of years, generous treatment should be accorded the site. The soil should be double-dug, taking care not to bring the under spit to the surface if it is at all clayey. Raspberries are essentially surface-rooting plants and enjoy a fairly light soil suitably enriched. Popular varieties for summer fruiting are Superlative and Baumforth's Seedling, while a new sort noticed this season named Pyne's Royal carried a wonderful crop of excellent quality. It also proved of vigorous growth. Established beds should be lightly forked over and a surface dressing of well rotted manure added.

Fruits Under Glass.

Strawberry Plants in Pots.—Pots of these which have been standing in the open will now benefit by being removed to the shelter of a cold frame, plunging the pots to the rims in ashes or leaves. Ventilate freely during fine weather.

Peach Trees.—After the leaves have fallen from the trees the work of pruning and thinning the shoots may be taken in hand. At the same time the house should receive a thorough cleansing. After the pruning is finished gather up the remaining shoots and tie them loosely together so that room may be made for washing the glass and woodwork, which should receive most careful attention, especially where, during the summer, red spider was troublesome. The walls should also be limewashed, or should the spent material from the acetylene gas plant be procurable it will prove an excellent substitute, being adhesive and also acting as a disinfectant. It does not scale off like ordinary lime or cement wash. After the work of cleaning the structure, the shoots should also be sponged with an approved insecticide, being careful to see that it is not applied strong enough to injure the buds. The older branches may be washed with a stronger solution.

SUMMER COLOUR IN THE SHRUBBERY

THE average shrubbery is lamentably short of summer colour. The great bulk of flowering shrubs blossom in or near the month of May. Many garden-lovers greatly appreciate the massed colour of Broom, Gorse, Barberry and Lilac, which each spring affords and are loath even to water this effect to admit of summer colour. For ourselves, we think this a mistake, believing that a sufficiency of colour to please almost anyone may be obtained in spring and yet far more of summer interest be introduced than is generally the case. One very satisfactory way of introducing summer colour is by planting drifts of herbaceous plants among the shrubs. This point has been recently dealt with in our columns. There is no necessity, therefore, to traverse that ground on this occasion.

The most striking of late-summer-flowering shrubs is undoubtedly *Buddleia variabilis*. There are several distinct forms of this which, in the garden, intercross freely, so that if self-sown seedlings are allowed to mature one soon has a whole constellation of slightly differing forms which, as a rule, are little, if at all, inferior to the parent plants. All are beloved of coloured butterflies and other insects. The best and most distinct forms in commerce are called respectively *Veitchiana*, *magnifica* and *superba*. *Veitchiana* resembles, as far as flower-colour goes, the original and very inferior form first introduced to English gardens, but is much finer in habit of plant and as regards size of truss. *Magnifica* is much more violet of hue and perhaps, of the two, the more desirable. *Superba* is somewhat like *magnifica*, though slightly paler in tone, fatter and larger of truss and, distinct advantage! quite a fortnight later to flower. It is usual to prune these *Buddleias* very hard in spring, removing

all old wood and cutting back the young to a few eyes, exactly as one treats *Hydrangea paniculata* in fact. Such pruning undoubtedly tends to produce extra fine blossom trusses, but is not essential. The plants make enormous growth and flower freely and handsomely if left quite unpruned. Readers will appreciate that for some situations plants should not be too sophisticated.

As *Hydrangea paniculata* has been mentioned it may be as well next to consider the *Hydrangea* family, for its members are all summer-flowering and exceedingly valuable in the garden. The sterile form of *Hydrangea paniculata*, *H. p. grandiflora*, is the member of the family most commonly met with in gardens, though the typical *H. paniculata* is more graceful, and *H. arborea* far

provocation is necessary for the coloured forms to come blue. They are then most welcome, as blue shrubs are scarce. The deep coloured forms are especially worthy, and, seen among the changing lights of woodland, are very beautiful. The pure white forms are not to be despised, however, and the fine trusses of *Mme. E. Mouillière* are particularly noteworthy. Closely related to these *Hortensias*, and probably rather hardier, *H. japonica* is well worth growing where it will "stand" outdoors.

Hardy *Fuchsias* are a general standby for summer blossom. Only near the coast do they retain sufficient wood through the winter to be treated as shrubs, but they break from the bottom each spring in all but the very coldest localities. Most of them are forms of *F. macrostemma* and differ mainly in

the size of the plant and its component parts. *F. Riccartoni* is, many think, hardiest of all, but it is less free flowering than the *macrostemma* forms. The red and white hybrid *Mme. Cornelson* seems hardier as a shrub than the supposedly hardier species and sub-species, but it shews less power of recovery if cut to the ground.

The shrubby *Veronicas* are exceedingly valuable for summer flower. Like many races of plants from the Antipodes they are suspect as regards hardiness. Several species, however, are equally as hardy as many other regular inhabitants of our shrubberies. *Veronica Traversii* is perhaps sufficiently showy to be worthy of notice as summer flowering,

A SPRAY OF *EUCRYPHIA PINNATIFOLIA*.

more floriferous. This latter is not white, however, but a greenish cream colour, effective none the less in the mass and admirable associated with crimson *Fuchsias* or with *Buddleia variabilis* or purple *Veronica*. In the southern counties or near our seaboard the now numerous forms of *Hydrangea hortensis* prove hardy. On some soils no

though it lacks, of course, the grace and beauty of the far less hardy *V. Hulkeana*. This latter withstands average winters outdoors in the Midland Counties, but except in the moister and more congenial climate of the West, does not properly develop its lavender panicles outdoors. There are now many beautiful forms and hybrids of *Veronica*

VERONICA DIEFFENBACHII WITH PURPLISH FLOWERS.

A FREE-FLOWERING ROCK ROSE, CISTUS CRISPUS. THE BLOOMS ARE PURPLISH ROSE.

A RATHER UNCOMMON BROOM, GENISTA CINEREA.

speciosa, but this is a tender species, though a quick growing and easily propagated one. It stands outdoors, however, unless in exceptionally severe winters, anywhere south of London and, naturally, anywhere near the sea. The crimson Simon Delaux is especially beautiful, so is the wonderful violet blue Mlle. Delaux, but there are many other charming varieties. The nearly related *Veronica Dieffenbachii*, now illustrated, has purplish flowers and withstands about the same amount of inclement weather. Perhaps the most striking of these shrubby Speedwells is the aptly named *V. salicifolia*, for the leaves do indeed resemble those of some of the true Willows—*Salix vitellina*, for instance. The rather twisted spikes of pure white are large in themselves and abundantly produced and shew to advantage against the glossy foliage. This very hardy species reproduces itself freely from self-sown seeds. Somewhat like this species, but much smaller, is *V. angustifolia*, which forms neat little bushes for the forefront of the shrubbery. Species smaller than this need not be considered here for they pertain rather to the rockery than the shrubbery. There is a multitude of hybrid forms, however, with more or less claim on our attention. Among these is the deep violet, semi-prostrate Autumn Glory. This is free to flower and produces a succession of blossoms, but the individual spikes are very small. It hybridises freely (and without artificial assistance) with *salicifolia*, *angustifolia*, *pinguifolia* and the *speciosa* forms, and many of these natural hybrids are quite beautiful. Given the opportunity it would probably hybridise with *glaucophylla* and other small species and possibly with *V. Traversii*. *Veronica Andersoni* is said to be a cross between *V. speciosa* and *V. salicifolia*. Its variegated form is one of the handsomest of variegated shrubs, but, unfortunately, even less hardy than the forms of *V. speciosa*.

The beautiful *Euryphia pinnatifolia* is generally supposed to like peaty soil—but it will grow even in stiff clay! This glorious shrub (or small tree) is, unlike the *Buddleias*, for instance, quiet and restrained in its beauty, but amazingly attractive. There are those who think *E. cordifolia* even more beautiful—high praise indeed. This species is, however, hardy only near our seaboards, whereas *pinnatifolia* seems hardy everywhere.

Some little while ago we published an article on late-flowering Brooms (July 15, page 349). The best are, no doubt, *Genistas atrensis*, *cinerea* and *virgata*, and *Spartium junceum*.

If the hardy Heaths had no other claim to consideration the fact that a number of species and a multitude of varieties flower in summer would make them useful for the shrubbery where the soil is at all suitable for their culture. The Heaths are too big a family to be dealt with at all comprehensively in such an article as this, so that an almost bald list of a few of the better sorts must suffice. The Cornish Heath is exceedingly valuable on account of the long period during which it remains in flower. The choicest form, *Erica vagans* St. Keverne, with salmon blossoms, is still scarce. The varieties *alba* and *grandiflora*, though rougher, are quite good. *Erica cinerea* flowers earlier, but some varieties, notably the compact *coccinea*, are very brilliant. Var. *atropurpurea*, of a deep reddish purple hue, is also valuable and a robust grower. There is, too, a pure white variety. The cross-leaved Heath, *E. Tetralix*, though a very common wilding, is valuable for massing. The variety *mollis* is very distinct and remarkable, with white flowers and greyish white foliage. Mackay's Heath is closely related to the last species. It is a handsome rosy-red sort. There is a double form of this, said (Bean, "Trees and Shrubs") to be longer lasting than the type.

To be concluded.)

PROGRESS WITH THE BEARDED IRIS

BY JOHN C. WISTER, *President, The American Iris Society.*

I HAVE had the pleasure this year of revisiting a number of the chief Iris gardens in France and England and of seeing the great improvements that have been made in them in the past three years. The nurseries and gardens are now again in first-class condition, and the Iris breeders have produced many new seedlings of surpassing beauty.

The reason, or rather the excuse, for my trip was to attend the Iris Conference in Paris on May 27. On the day of the Conference a number of fine new varieties were shewn, the best probably being some of the new seedlings from Cayeux and Le Clerc. Three of these—Belisaire, Jean Chevreau and Grand Ferre—received certificates of merit, and they were very fine Irises judged from any point of view.

The next day, with Mr. Wallace, Mr. Dykes and others, I went to the Cayeux nursery and saw there a dozen or fifteen very fine seedlings,

inclined to put it right up at the top in the class with Souv. de Mine, Gaudichau, Swazi and Bruno. I was much taken with this variety three years ago, and I am more and more impressed by it each year. Ballerine also shewed up well, but Magnifica, the largest of all Irises in general commerce, to me at least is somewhat of a disappointment, as it is so floppy. The unique colour of Medrano again attracted me, but the newer Vilmorin varieties did not seem to me of such great importance. I will want Trianon, Turco and Zouave in my own garden, where I can judge them more carefully, but I do not expect to find them as high class as Ambassadeur, Ballerine and Medrano. It is a disappointment to me that the Vilmorins do not introduce Allies, as this seems a very unique colour. I am told it has bloomed four or five years in succession in October, so that it looks as if it might be the beginning of an Autumn-blooming strain.

as good as Mlle. Schwartz, which received an award at the Paris show. His varieties have a tendency to have weak stems and need more careful selecting. Mr. Bonnewitz tells me that his new variety Louis Bel is one of the most beautiful of all dark Irises. It is a Gaudichau-Kochii cross.

In England I saw Irises at two flower shows and in a large number of gardens and nurseries. Wallace's exhibits, both at Chelsea and on June 7, were the finest I have ever seen. There can be no doubt about the value of Swazi, Cardinal, Bruno and Duke of Bedford under English conditions. I would be afraid to recommend them in America until they have been more tested, as Dominion with us has been a disappointment in many places.

The same holds true with many of Sir Arthur Hort's seedlings, but where they can be grown I predict a wonderful future for Leonato, Shylock, Blanche, Willoughby and five or six others. His continued breeding with Caterina, Cypriana, Mesopotamica and Ricardi have given him wonderful height and size, and apparently he has got away from the crooked stems which are characteristic of Denis's Ricardi seedlings. He has made wonderful progress since I saw his seedlings in 1919, even the beautiful Ann Page and Volumnia being left far behind by his newer ones. His garden is on a steep slope, and is underlaid with chalk, so that the Irises have just what they want; The view of the neighbouring church and of the fields and trees and hills in the distance is as charming as any garden outlook I have seen.

I was perhaps more astounded by Perry's seedlings than by anything else I saw on my trip, for while I had recognised for years Mr. Perry's work with Delphiniums, Poppies and other plants, I had never considered him seriously as an Iris breeder, in spite of the fact that he had given us many good varieties like Her Majesty, Black Prince, King George V and Wm. Marshall in the past. One glance at his nursery this year convinced me of my mistake, for he has as wonderful a patch of seedlings as I have ever seen, all of extraordinary height, of good form and fine clear colouring. His trouble is going to be selecting them so that only the very best will get into cultivation. There is always a temptation to name too many, and this has worked harm to the reputations of many of our breeders. When I saw them they were all under numbers, but at the Royal Horticultural Society's Show on June 7 three of the best were named Benrimo, Marion Cran and Robert Wallace.

I was greatly disappointed not to see the Perry varieties which had won such fine awards in 1921, but they had evidently been cut up too much to bloom. I cannot imagine that they are as fine as the seedlings which I did see and among which a flower almost the duplicate of Archeveque, but as tall as Alcazar, stood out.

My visit to Mr. Bliss in Devonshire was a most delightful one, although I did not here see as many important novelties as I had hoped for from Mr. Bliss' past performances. It was worth the long journey, however, to see Pioneer, a variety descended from Germanica and having some of the earliness of that species. I should say its colour was somewhere between Gaudichau and Parc de Neuilly. This should be a most important addition to our gardens. Citronella, which has won such high awards, did not excite me as much as I expected, nor did Susan Bliss, although I am willing to admit that it may be one of the best,

IRIS TIME.

among them Eclairer, Glorie, Imperator, Liberty, Peau Rouge, Salonique (which had received honours in Paris in 1921), Marc Aureau, Mme. Henri Cayeux, Mme. Abel Chatenay, Fidelio and Mrs. Robert Wallace, the latter being named that day because Mr. Wallace admired it so. These are going to make the name of Cayeux important in the next year or two, and are going to give the English breeders something to think about and to strive to outdo. If we consider that Ma Mie, sent out by Cayeux and Le Clerc sixteen years ago, is to-day more important than the day it was sent out, we can see that Cayeux knows something about Irises, and when he makes his final selection I am sure it will be a good one. The plants are all grown in the small walled-in garden at Vitry only a few miles from Paris, and presented a brilliant display of colour against the old grey walls.

On Monday, May 29, we were all invited to the Vilmorin's nursery in Verrieres to see their new things, and their fields were indeed a fine sight. The more I see of Ambassadeur the more I am

The grounds at Verrieres were spotless, and we had a chance to see not only the new Irises, but the old ones, and to be impressed with the great progress that this flower has made. A delightful lunch was served to about forty guests, who were most gracefully welcomed by Mme. Phillippe de Vilmorin.

At Millet's nursery in Bourg-la-Reine, of course, the outstanding variety was Souv. de Mine, Gaudichau, which Mr. Wallace has proclaimed the finest variety ever grown in France. Certainly no garden should be without it. Each year I am more and more impressed by the excellence of some of the other Millet varieties, which have as yet not attracted the attention they deserve. I refer particularly to Corrida, Delicatissima and Col. Caudelot, all of them free blooming, of excellent colour and fair height, but all of them apparently ignored in the race for giants. They can be had at reasonable prices, and are far superior to many much more advertised kinds.

We saw also in and around Paris a number of Demis seedlings, but none of the new ones seemed

if not *the* best, of our pinks. I can promise Mr. Bliss however, that it is going to have some real competition with a number of American seedlings of that colour, among them May Rose, Dream and Wild Rose.

I saw a number of Bliss seedlings also at the Whitelegg nursery in Orpington, where Moa and Clamour stood out. There, also, was a very fine mass of Tamar, a variety which has rather disappointed us in this country. It is not much as an individual flower, but it makes a magnificent mass, and should be in great demand when it gets cheaper.

At Mr. Bliss' also I saw a number of new Dominion race seedlings, but while they may technically have improvements over Cardinal and Duke of Bedford, these improvements are not such as to make it worth while for the gardener to bother with them until they have gone a step further; in other words, they are too close to existing sorts. This, of course, is a common fault of Iris seedlings everywhere. I notice in this country since coming home that the reaction is setting in and that people are refusing to buy new sorts until they see them.

In Mr. Baker's garden at Bexley I had the pleasure of meeting Mr. Yeld and seeing some of his finest seedlings, the best of all of which was Asia, which was a most magnificent flower. I had admired a few plants of it at Chelsea, but Mr. Baker had a mass of it more than 10ft. long by 2ft. wide, and I think in this mass it surpassed any variety I have ever seen anywhere. He also had a splendid mass of his older Lord of June, and I am still ready to stick up for this variety, which excited me so much when I first saw it five or six years ago. Big masses of Lord of June, Halo and Neptune made one wonder which was the best. I have never been able to decide.

At Mr. Baker's also was the finest Dominion I have ever seen. It stood 3ft. in height. I heard some criticism at the R.H.S. Show on June 7 that Dominion was no better than Black Prince. With all due respect to the people who said this, they could never have seen a first-class Dominion. Black Prince as shown at the Royal Horticultural Show was very fine and fully equal to a poor Dominion. The show at the Royal Horticultural Hall was certainly a wonder. Mr. Wallace's table was to my mind by far the best. Mr. Barr's also was very fine, and would have been still finer if he had eliminated about twenty old varieties which were no good. I noted at that Show several tables which were ruined by shewing what in American vernacular we call "junk." Splendid Irises like Alcazar and Ambassadeur and some of the new Bliss varieties were interspersed with Honourable, Duchesse de Chantefort, Comtesse de Courcy, Mexicana, Harrison Weir, Faustin and other old sorts which have been superseded for quite twenty years. In one case at least I am sure this nurseryman could have received a prize if he had taken twenty vases out of his table and left the rest. They killed the exhibit.

We were glad to see the competition for the American Iris Society medal interest an amateur, and I for one was sorry that he did not win it, as he came so close to doing. In America our shows bring out a great number of amateurs, and while we do not have the wonderfully large exhibits of skilled professionals that you have in England, we feel that we are ahead in interesting the amateur in this flower.

The American visitors can never cease to thank the French and English for the hospitable reception which were tendered to them. Everywhere we were received with the greatest of kindness, and I do hope that many European Iris growers will be able to visit some of our American Iris shows and give us a chance to return the hospitality.

A ROCK GARDEN IN AUTUMN

It is regrettable that more attention is not paid to late summer and autumn effect in the rock garden.

WITHOUT including the many early flowering rock garden plants which will, in favourable circumstances, produce a sprinkling of bloom in autumn as a kind of farewell to summer, there are a goodly number which, from nature or habit, will give a good show of colour right on to the brink of winter. Thus an idle tour of inspection around the garden during the third week of October revealed several clumps in various situations of *Oxalis floribunda alba* in full flower, and this, oddly enough, several weeks after the entire foliage of the rose-coloured type had disappeared. Another very beautiful species of this family, *O. lutea*, with large cowslip-like heads of flowers in glistening gold, grows here like a weed and is never out of bloom from May to December.

Ceratostigma plumbaginoides is another late bloomer which loves to send its roots among buried stones and which, once it is thoroughly established in a light, warm soil, will annually provide a mass of rich blue flowers above its crimson-tinted foliage. In a paler hue is *C. Willmottiana*, and this is taller and of more bushy habit, but that it is an improvement on the older form all will not admit. Another fine patch of blue may be found in a cool corner where *Geranium Wallichianum* var. *E. C. Buxton* is sprawling in elegant disorder, and the few flowers which one may always expect to find in a bed of *G. grandiflorum* will invariably be a purer, more arresting colour than those of summer. Another fine *Geranium* that will carry a head of bloom well into these last days is Russell Prichard.

That little sun-worshipper, *Verbena chamaedrifolia*, which almost startles one with the brilliance of its scarlet, white-eyed flowers, is also a dependable autumn bloomer. The same may be said of *Verbena venosa*—never to my eye so pleasing massed in the bed as it is in the rock garden of poor hot soil, where, if shorter in stature, it is larger in the flower-head and of a more sumptuous purple. This is a much hardier plant, by the way, than is generally supposed. Two *Convolvulus* always blossom freely here during these late days, namely, the silvery-leaved *C. Cneorum* and the trailing *C. mauritanicus*, whose delicate charm needs no word of praise from me. Yet another lovely, if common, thing is *Corydalis lutea*, a plant whose fragile beauty is apt to be overlooked in gayer days.

Pentstemon heterophyllus, which will sometimes survive a winter in the open with us, will give a brave show of its amazing trumpets in varying shades of blue and amethyst gleaming with an opalescent sheen until the last, provided the weather remains kindly. Then there are the *Linarias*, a genus which provides a number of good autumn bloomers, though most of the creeping kinds are too rampant and overwhelming to be admitted among the more orderly denizens of the rock garden. Two of these, yea, three, must however be afforded a place for their undeniable beauty and, happily, they are not the most difficult to keep within bounds. These are the tiny *L. aquitriloba*, a minute clinging creeper with lilac flowers, *L. pallida* in lilac and white and its pure white variety *L. p. alba*. The blossoms of the last two are the largest among those of this class, and they are borne profusely among strikingly handsome foliage. Of quite another kind is the indescribably lovely *L. alpina*, which is everyone's friend, one of the most delightful alpinists ever introduced to

English gardens. Then if one's rock-gardening principles do not forbid an indulgence in annuals (and why should they?), the *Linaria* family will provide a number of excellent little species and hybrids, among the most charming of which is the chocolate and golden *L. multipunctata*.

Dianthus Carthusianorum is sometimes called hard names, but both it and such others of its class as *D. cruentus* and *D. atrorubens*—which last is perhaps the best, though *Carthusianorum* is always the latest here—are not to be treated too indifferently these shortening days. They may lack many of the charms of the Pinks of midsummer, but they are the most weather-proof flowers I know, never plead for any attention, but carry on doggedly year after year, the Stoics of their happy race. And so it is with the Mule Pinks. There are rock gardeners who nurse the same antipathy for these bright and cheerful things as they do for annuals—because they are annuals. But there are others, to whose company I humbly belong, who have an appreciation for the *D. hybridus* group—always so faithful to their autumn-flowering reputation—which is not chilled by the knowledge that one of Napoleon III's parents was just a common Sweet William. At the moment of writing *D. hybridus roseus* and the salmon-pink *D. striatiflorus* are among the brightest bits of colour in the garden.

There are always some flowers about the *Armerias* at this time of year, but there is not one of this race of pretty things known to me which will yield an autumn display as fine as that of earlier days as the variety known as Bees' Ruby Thrift. Two feet high, this splendid *Armeria* is now bearing its large vivid carmine-pink flowers, and there are enough buds still coming to maintain a succession for several weeks longer. The very antithesis of this blazing beauty is the autumn-winter flowering *Periwinkle*, *Vinca acutiloba*, whose large, clean-cut flowers, in a white so delicately suffused with just a hint of blue as to seem positively cold, peer out of the depths of the dark green foliage with a wan but penetrating light.

Lithospermum prostratum and its variety Heavenly Blue seldom fail at this time to break into a fuller bloom than they have borne since the later spring, and the gem of their tribe, *L. rosmarinifolium*, is just opening the first of its large and surpassingly lovely flowers, the first of a series which will be maintained during fair intervals until there is an unmistakable scent of spring in the air. The neat and bushy *Helianthemum* (*Cistus*) *lunulatum*, with foliage of silver grey is covered with its little yellow flowers, the petals of which each have a tiny crescent of orange at the base, while of its kind *H. oelandicum* may be counted a worthy second in autumn flowering.

Not to be passed without respectful notice is the white-foliaged *Teucrium ackermerus*, a bushy and beautiful species which first opens its rosy crimson heads of flower at this season. Though the rock garden *Campanulas* have mostly had their day, *C. garganica alba* is always true to its reputation for late blooming, and there is a newer one, a *carpatica* × *rotundifolia* hybrid, known as *C. car-rotundi*, which has so far proved a most reliable autumn blossomer. The deeply and sharply segmented bells of this variety are of a peculiarly luminous sky blue, and the plant seems to be vigorous and easy. Spreading in wiry, prostrate sprays of grey foliage in a sunny corner, *Alyssum idæum* has adorned its tiny self with

clusters of bright yellow, and in a still more telling shade of the same colour are those exquisite little *Eschscholtzias tenuifolia* and *cæspitosa*, most lovable bantlings, the product of seed scattered at random about the rocks in June. *Thymus carnosus*, upright and stiff, with flowers of a dead white, represents its genus, and among the shrubby *Potentillas* which have made the best success of a late-flowering season are *PP. Farreri* and *tritica argentea nana*. *Geum Borisii* is also much in evidence, its orange-scarlet

being just the colour to respond to the golden sunlight of October, a colour which glows with a still intenser heat in the torches of the miniature *Kniphofias*, without which the autumn rock garden can hardly afford the fullest appeal. *N. Wales*. A. T. JOHNSON.

OWN ROOT CLEMATISES AT GRAVETYE

OF hardy climbing plants, the Clematises with their graceful and varied forms of bright and charming flowers are the most beautiful when grown to perfection. This notwithstanding, many of our gardens have been robbed of their presence through the unnecessary practice of grafting choice kinds upon the coarse stocks of the Traveller's Joy of our chalky hills and hedges. Thousands and thousands are propagated each year and, so grafted, sent out to customers to die.

I frequently visit gardens, but it is quite an event to come across a healthy Clematis. If one remarks upon their absence, the answer invariably is, "Clematises are so liable to die off suddenly—often as the flowers begin to expand—that we have given them up altogether." In order to get over this trouble considerable pains have been taken here over a period of many years, with the result that we now layer our own plants.

The layers are put down in March each year, being pegged to the tops of 6in. pots of sandy soil, which are sunk into the ground to the level of the border. By the following autumn the pots are well filled with roots, and the young plants are ready to be severed from the parent and transferred to fresh positions.

When new varieties arrive from a nursery their roots are thoroughly washed out, and

invariably two distinct sets of roots are to be seen, one the long fleshy root of the true Clematis and the other the roots of the wild stock, which we cut right away, leaving the plant to establish itself upon its own roots. From this practice we have had better results than when leaving the stock roots to them.

Clematises are grown here in quantities. Varieties such as *Perle d'Aznre*, *Nellie Moser*, *Ville de Lyon*, *William Kennett*, the *Nippon Clematis* and many others are scrambling over great bushes of *Magnolia* to a height of 20ft.; providing, over many months, a wealth of beauty such as could scarcely be surpassed. In addition to their association with host plants, we grow them largely upon walls, fences, tripods and pergolas; in all some thirty or more kinds. Some of these

PART OF A PLANT OF CLEMATIS PERLE D'AZURE ON ITS OWN ROOTS.

Established over 25 years, without protection.

plants have occupied the positions they fill to-day for over twenty years, producing thousands of choice flowers each year.

In its native habitat the Clematis is found on the fringes of woods, where its flowery growths, as they veil the natural undergrowth, are exposed to full sunshine, while their roots are shaded and cool. There are some other causes which will lead to the death of a plant, such as slugs barking the growths. Mice will damage them also, and even the wind, so fragile are their stems, but grafting is the great enemy.

Clematises growing in the open obtain great benefit from mulching, especially during long spells of drought, and I have known healthy stems to develop new roots up to 6ins. above ground-level.

Although the Clematis is essentially a plant of calcareous regions, it will succeed in ordinary soil. At Gravetye, when making fresh plantations, the soil, 3ft. deep, is made up of loam and leaf-soil with a good proportion of sand. Nothing is added after planting but a mulch of bracken, no manure being given.

I have frequently noticed that where plants on their own roots have, from one cause or another, been damaged above the ground line during their early growth fresh young wood quickly appears and fills the vacancy.

There is thus ample proof here that the loss of this precious group of climbers of the northern world in the gardens and nurseries of Europe is wholly due to the practice of grafting Japanese and Chinese kinds on the wild Clematis of our chalk hills, and in France on *C. viticella*, a native of that country, both equally harmful. E. M.

CLEMATIS ON OAK TRELLIS BEHIND A MIXED BORDER AT GRAVETYE.

NOTABLE NOVELTIES AT VINCENT SQUARE

IT was supposed to be an Orchid Show at Vincent Square on October 31, and the growers of these flowers came in great force. The amateur orchidists were induced by the special offer of challenge cups presented to the R.H.S. by the trade. Mrs. Mary Joicey had a very attractive group in which the beautiful blue *Vanda cœrulea*, many *Cypripediums* and *Sophran-Lælio-Cattleyas* were prominent. Sir Jeremiah Colman included a number of *Odontoglossums* and *Cattleyas*, particularly a large plant of *C. Bowringiana lilacina*, which in the spike had much the appearance of an unusually large *Dendrobium*. Mr. H. E. Pitt also had a beautiful collection.

Messrs. Charlesworth and Co. staged a very large display of *Odontoglossum crispum xanthotes*

H. E. Converse, Mrs. S. Dove, Mrs. G. Monro, jun., and the new Viscount Chinda in this and Messrs. Wells' collection were especially imposing, though many admired the grace of the spray blooms and those with anemone centres—*Thora* of rosy mauve colouring, and Mabel Weston, a dainty blush.

Another gold medal exhibit was the splendid collection of winter-flowering *Begonias* from Sir Charles Nall-Cain, *The Node*, *Welwyn*, and this filled a whole length of tabling. Nearly all of the exceedingly floriferous plants were growing in quite small pots. *Ideala*, deep old rose colour; *Scarlet Beauty*, semi-double of drooping habit; *Emita*, orange; and *Flambeau*, rich orange semi-double, are only a few of the fourteen sorts on view.

Messrs. Allwood Brothers, Messrs. Stuart Low and Co. and Mr. C. Engelmann.

The winter value of many alpine was well illustrated by Messrs. G. G. Whitelegg and Co., who filled a whole length of tabling with pots and pans of very neat plants. Some of them, such as *Saxifraga hybrida*, *S. Aizoon* and *S. pectinata*, had an attractive reddish bronze on the outer leaves, but it was the intense silveriness of *Teucrium aureum*, *Raoulia australis* and *Saxifraga longifolia* that attracted most attention. Anyone with a cold greenhouse to spare would be well advised to have a collection of such alpine, if only for their winter beauty.

Among other hardy plants Mr. G. Reuthe had flowering sprays of the uncommon *Hoheria populnea* and *Salvia Grahami*. The latter is a

ALMOST MARY RICHARDSON COLOUR, CHRYSANTHEMUM
MISS A. HAZELL.

A VERY PROLIFIC NEW WHITE PERPETUAL CARNATION,
THOMAS C. JOY.

in quantity and many other crispum varieties. Messrs. Sander and Co. showed the beautiful *Vanda cœrulea splendida*, while Messrs. A. and J. McBean included *Oncidium* and *Odontoglossum* of merit and Messrs. J. Cypher and Sons gave prominence to many *Cattleyas* and *Cypripediums*. Messrs. Charlesworth and Co. and Messrs. McBean were awarded gold medals.

The *Chrysanthemums* were to a great extent composed of the large exhibition Japanese varieties, and for an excellent collection Mr. H. J. Jones won his sixth gold medal of the year which certainly must constitute a record. The huge blooms of such sorts as Mrs. R. C. Pulling,

In the collection of stove plants by Messrs. L. R. Russell, Limited, there was a plant of the rich blue *Tillandsia Lindeniana* which attracted a deal of attention. In former days these Bromeliads were often grown in our hot-houses, but they are now very rare. Another comparatively rare glass-house plant to be seen at the hall was the white, double-flowered *Primula*, of which General Sir Charles Hadden sent up a number of fine plants. For a very long time the old double *Primula* had to be raised from layers, but now a good strain of seed can be relied upon to produce a great proportion of double flowers. Carnations were, as usual, very beautiful in the collections of

beautiful little bush for the herbaceous border, though it is not entirely hardy in most districts. Mr. J. J. Kettle had bunches of large, fragrant Violets with his late Raspberry Lloyd George, still fruiting abundantly.

A very good collection of Grapes was sent by the Hon. Vicary Gibbs, and these were staged with great skill. The chief white sorts were *Muscad of Alexandria* and *Lady Hutt*, while among the black Grapes were *Appley Towers*, *Black Aheante* and *Gros Maroc*. The R.H.S. had Beetroots from their Wisley trials. There were fourteen sorts and all of the long shape, and while all were well grown, one selected Dobbie's Purple and

Dell's Crimson-leaved on account of the fine, dark colour of their roots.

NEW AND RARE PLANTS.

Berberis × Lady Beatrice Stanley.—This is a most lovely Barberry. It has somewhat the habit of *B. Wilsonae* and the autumn foliage

GLOWING BERRIES OF BERBERIS LADY BEATRICE STANLEY.

colour of *B. Thunbergii*, while it bears almost a superabundance of bunches of roundish rich coral pink berries about the size of Sweet Pea seeds. The most critical need not have demurred had a first-class certificate been given. Award of merit to Lady Beatrice Stanley.

Carnation Thos. C. Joy.—This very fragrant, white perpetual-flowering variety is of medium size, fully double, and has serrated edges to the petals. Award of merit to Messrs. Allwood Brothers.

Chrysanthemum Miss A. Hazell.—A perfectly formed single variety of Mensa type and very uncommon orange terra-cotta colouring with a rosy sheen. R.H.S. award of merit and N.C.S. first-class certificate to Mr. G. Carpenter.

C. Mrs. B. Carpenter.—A very beautiful Japanese bloom of the largest size yet particularly graceful form. It measures roins. across and gins. deep. The long, broad florets reflex at the tips and the colour is a charming shade of soft rosy pink. R.H.S. award of merit and N.C.S. first-class certificate to Mrs. B. Carpenter, Crouch End, Finchley.

C. Wycombe Pink.—A large, graceful single soft pink Chrysanthemum. The narrow petals are attractively reflexed at their tips. Award of merit to Mr. W. H. Tyzack.

Croton Lord Balfour.—A very beautiful seedling raised by the exhibitors. The long, fairly narrow leaves have very uncommon red markings on bronzy green ground. Shewn by Messrs. L. R. Russell, Limited.

Crataegus Fulleriana.—This appears to be a hybrid between *C. Crus-Galli* and *C. coccinea* which, as shewn, lacks the grace of *coccinea*. Stiff, leafless branches bearing large bright scarlet haws, perhaps a trifle larger but not so bright as those of *C. coccinea*, were on view. The branches have occasional stiff spines. Award of merit to the Hon. Vicary Gibbs.

C. Ellwangeriana.—The above remarks apply to this except that the fruits are a trifle duller

in colour. Many planters will prefer *C. coccinea* to either. Award of merit to the Hon. Vicary Gibbs.

Pelargonium Fascination. As a pot plant this did not fascinate us, but some greatly admired the cut trusses in the floral decoration, where the small, scarlet, cactus-like flowers were moderately effective. It is said to be a seedling

plants on view were especially vigorous, and the leathery, lanceolate, very spiny leaves were much longer than usual. Each plant had in its centre the characteristic, compact, round head of soft pink flowers studded with pale orange stamens. Shewn by Messrs. Barr and Sons.

Salvia Lord Lascelles.—If well grown this might be a useful variety of the well known *Salvia splendens*. The colour is an uncommon pale salmon pink. Shewn by Mr. J. H. Crosby.

S. Princess Mary.—Another variety of *S. splendens*, but of better habit, though the pale primrose yellow corollas and paper white calyces are not likely to attract many gardeners. Shewn by Mr. J. H. Crosby.

Lælio-Cattleya Venada.—A large bloom in which the sepals and petals are stippled with mauve and the broad orange yellow lip is margined with the same shade of colour. Award of merit to Mr. H. T. Pitt.

Lælio-Cattleya Dodona.—This is a wondrously beautiful flower of large size. The sepals and petals are of golden buff colour, heavily stippled with rosy purple, while the broad, velvety purple lip has an orange throat. First-class certificate to Messrs. Cowan and Co.

Odontoglossum crispum Beauty Spot.—A particularly fine variety. It has silvery white sepals, the lower pair are lightly flushed with purple, and there is a large brick red blotch on each segment. First-class certificate to Mr. Pantia Ralli.

O. crispum Silver Moon.—A charming silvery white flower of good shape which has a small pair of pale chocolate blotches on the lip. Award of merit to Mr. Pantia Ralli.

O. Princess Yolande Gerrish's var.—A large spike of well formed flowers heavily marked with chocolate. Award of merit to Mr. R. Gerrish.

Vanda luzonica var. dulcis.—Although, no doubt on account of the cold weather, we did not detect any sweetness, the flowers are quaintly beautiful in their somewhat hooded appearance and lilac markings on a white ground. First-class certificate to Messrs. Sander and Co.

THE CRIMSON FRUITS OF CRATÆGUS ELLWANGERIANA.

THE IMPERIAL FRUIT SHOW

THE exact appeal of this, presumably, annual fixture to the general public is not obvious. Perhaps the War Museum and other side shows at the Crystal Palace form part of the attraction. Certainly it is not easy to imagine anyone not a market grower or retail fruiterer, becoming enthusiastic about scores and hundreds of boxes of Apples and Pears as packed for market. The cider makers' exhibits were exceedingly interesting

The Apples included fine dishes of Charles Ross, King of Pippins, Duke of Devonshire (green russet), Royal Russet, Allington Pippin, Peasgood's Nonsuch, Warner's King and Bristol Queen. Among the Pears the quite round fruits of Buerré de Naghan were noteworthy.

Messrs. Laxton's admirable exhibit included fine dishes of, among many others, Rival, Newton Wonder, Coronation, Laxton's Superb, Peacemaker and Rev. H. Wilks Apples and Diamond Plums,

MESSRS. LAXTON'S ATTRACTIVE EXHIBIT.

in their way, so were the British nurserymen's exhibits of fruits in a more usual setting, but the cold, draughty atmosphere of the Palace and their remoteness one from another, took from the effect even in their case.

Messrs. Bunyards had a wonderfully fine exhibit of Apples and Pears, though, largely owing to the position allotted, it was less attractive than their magnificent group at the Great Autumn Show at Holland Park. Their Pears included Pitmaston

the latter on close inspection shewing signs of shrinking.

Messrs. Brambers of the Norfolk Nurseries shewed lifted plants of various fruit trees, Roses, etc., all clean, healthy stuff. The Barnham Nurseries had an interesting exhibit consisting, on the one side, solely of market varieties, but on the other, we noted good dishes of such Apples as Alfriston, Charles Eyre, Orleans Reinette, Ribston Pippin, Egremont Russet, Cox's Orange Pippin

THE KING'S ACRE NURSERIES WORTHILY REPRESENTED THE MIDLAND COUNTIES.

Duchess, Catillac, Doyenné du Comice, Buerré diel, Emile d'Heyst, Double de Guerre, Roosevelt (an immense and highly coloured dessert sort), and Buerré Alexandre Lucas, all of admirable quality. Among a great variety of Apples, Rev. W. Wilks, Ellison's Orange and Peasgood's Nonsuch caught the eye as especially good.

Messrs. Seabrook's exhibit consisted of boxed fruits, and in another place, of specimen fruit trees in tip-top condition.

The King's Acre Nurseries had a large and representative collection of Apples and Pears,

and Brownlees Russet. Their Conference Pears were also very good.

Messrs. Isaac House and Sons made quite a display with their new Apple, John Standish. The big Covent Garden salesmen were, as usual, well represented, notably Messrs. T. J. Poupard and Messrs. Geo. Munro.

Mr. W. Wells, Junior, provided in one part of the hall some of the lightness and variety which was so sadly wanting elsewhere. He had a charming arrangement of Delphiniums and Scabiosa caucasica. We can only hope that his enterprise was

rewarded. Messrs. Carters of Raynes Park had an attractive mixed display of dry bulbs, vegetables and garden sundries.

Upstairs, in the gallery, there were the usual scientific exhibits of the Ministry of Agriculture and the various experimental stations. We noted, besides, on the attractive stand of Messrs. W. Darlington and Sons, Limited, the Titan Horti-Plow, a cheap and handy tool, which should be very useful in gardens of any size, and the M. P. (Motor) Mower-pusher. So far as appearances go, both these appliances should be eminently useful. Messrs. Darlington exhibited in addition a great array of garden sundries, Nicotine preparations and what not!

Messrs. Abol, Limited, were, as usual, well to the fore with their specialities, such as Stictite (their admirable banding compound), "Limsul" (lime-sulphur wash), Abol (the excellent general insecticide), etc. Their excellent patent syringes and spraying machines were also on view. The Wilkinson Sword Company shewed their sword-steeled pruning shears and other sundries.

APPLE ALFRISTON

ON account of the extraordinary heavy crop of Apples we had in 1919, so that we could afford to lose some, it was decided that several experiments be tried to ascertain the best methods of keeping them in good condition for a lengthened period. Some of these experiments were successful—most were not.

One of the trials was to wrap each Apple in brown paper, and at the time of storing no particular variety was selected for this purpose, except those which, in the past, were considered good keepers when laid on the shelves in the ordinary way. On the present occasion, the fruit-room was filled to overflowing, Alfriston being among the last to be picked. As it is a large Apple, one did not grudge the time for wrapping so much as might have been the case with a small variety.

It is not necessary to remind fruit-growers that dry days only should be taken advantage of for storing Apples. When picking fruit from high trees I wear a strong apron securely fastened over the shoulders, as well as tied round the waist. The apron should be long enough to double up so that it can be strapped to the waist, leaving both hands free. It is so important that the fruit should not be bruised or damaged in any way.

Our Alfristons were taken to the fruit-room and each wrapped in a square of brown paper and packed away in a section of the house as carefully as if they were intended to be sent to New Zealand. With the exception of a cursory examination of one or two on the top of the pile, they were not again looked at till May of the following year, the house by that time being cleaned out of all the best samples.

Alfriston is a superior cooking variety, and when Apples were plentiful no one would think of eating it raw, but after being stored away in this way it was so beautifully coloured and so attractive to look at that some were sent to the table for dessert, and it was no surprise to us to be told they were so good they must all be kept for eating.

As our crop in 1920 was the most wretched we have had in twenty-five years these Alfristons were used as sparingly as possible, and a year after being stored we had them quite sound, though slightly shrivelled.

PETER McCOWAN.

Argomery Gardens, Kippin, Stirling.

CORRESPONDENCE

THE TWELVE BEST SHRUBS.

YOU ask me for a list. I will give you two lists. First, what your correspondent asks for, twelve good shrubs for massing, not trees. The other list is twelve trees and shrubs, all of the highest quality when well grown under favourable conditions. Both lists are alphabetical.

List I.—*Berberis Darwinii*, *Cydonia Knaphill* Scarlet, *Erica carnea*, *Hydrangea hortensis*, *Kalmia latifolia*, *Lavender*, *Magnolia stellata*, *Rhododendron Loder's White*, *Rhododendron (Azalea) Gloria Mundi*, *Rhus Cotinus*, *Rosa Moyesii*, *Viburnum tomentosum Mariesii*.

I have endeavoured to select a list of shrubs fairly easy to obtain and easy to grow, but such a list must largely be a matter of domicile and taste. I select *Rhododendron Loder's White* as probably the best white *Rhododendron* (it is being universally listed by the trade now), but many people would prefer a coloured hybrid or a species! I take *Azalea Gloria Mundi* as a well tried orange Honeysuckle *Azalea*, but some people will turn to the obtusum section. *Cistus* and *Viburnum Carlesii* are too fugitive (in different ways). *Viburnum tomentosum Mariesii* I prefer to *V. plicatum*, but some will not agree.

List II.—*Acacia Baileyana*, *Berberis Darwinii*, *Embothrium coccineum*, *Eucryphia cordifolia*, *Hydrangea hortensis*, *Magnolia Campbellii*, *Prunus Cerasus Hisakura*, *Rhododendron Aucklandii*, *Rhododendron obtusum*, var. *Hinemayo*, *Rosa Moyesii*, *Rhus Cotinus*, *Wistaria*. In this list some plants are not hardy, but all are first-class in a suitable climate and position. *Acacia Baileyana* is hardier than many others and a most beautiful plant. *Eucryphia cordifolia* in good form is undoubtedly even more beautiful than *E. pinnatifolia*. No one who has seen a fine group of blue *Hydrangea hortensis* in a Cornish wood will refuse this plant a place. I hesitated between *Magnolia Campbellii* and *M. grandiflora*, but the former is undoubtedly a more arresting plant! The Double Cherry, *Hisakura*, may have competitors, but, personally, I place it first among the Cherries.

Rhododendron Aucklandii is probably the tenderest plant I name, but the quality is unequalled and I prefer it, though I am sure I shall not have universal support. Of *Azaleas* I turn to the soft silvery pink of the *Kurume* known as *Hinemayo*; this plant in a half shady place in a mild climate will give six weeks perfect colour in March and April. *Rosa sinica Anemone* is not so good in habit or in fruit as *R. Moyesii*. *Camellia reticulata* is just excluded. The others need no comment.—“SENEC.”

I AM reading with great interest the discussion on the twelve best flowering shrubs. Some lists have been very good, but others, I feel, would lead to sad disappointment to the ordinary

amateur. Our garden of three acres has a poor and sandy natural soil, and this place is rather high and cold. My list of twelve flowering shrubs is: *Pyrus japonica*, *Pieris (Andromeda) japonica*, *Berberis* (many beautiful varieties), *Forsythia suspensa*, *Azalea mollis*, *Lilac (Marie Lemoine or Souv. de L. Spathe)*, *Deutzia Lemoinei*, *Philadelphus (grandiflorus or Lemoinei)*, *Kalmia latifolia*, *Spiraea (white and pink)*, *Hydrangea paniculata* and *Buddleia variabilis*. Each one in its turn seems to me the most beautiful and beloved of all!—A. M. D., Surrey.

EUCRYPHIA CORDIFOLIA.

“In good form even more beautiful than *E. pinnatifolia*.”

IN the correspondence in your paper concerning the twelve best shrubs I do not recollect any mention of *Escallonia montevidensis*, which is, to my mind, incomparably the finest of our autumn shrubs. It begins to bloom in October and is now, after several sharp frosts, at its very best. The bright green lanceolate leaves are surmounted by large clusters of pure white cinquepetalous flowers gleaming as though they were the children of spring!—REGINALD RANKIN.

THE twelve best do not exist! How so? Because no two persons will be agreed as to the merits of any given dozen plants! This fact of opinions differing widely when it comes to

making a choice concerning a special gardening feature was well shewn a few years back by the correspondence and voting conducted by THE GARDEN on desert Apples. Individual likes and dislikes vary much, whether they concern the flavour of a fruit or the decorative merit of a shrub. As the old lady said when she kissed her pet cow, “There is no accounting for tastes.” However, the exercise of making a selection of the dozen best shrubs has been interesting, and I submit the following twelve: *Prunus sinensis rosea plena*; *Notospartium Carnichæliæ*, the Pink Broom, a real treasure for a garden; *Ceanothus Gloire de Versailles*, seen well at Kew as a massed shrub; *Cistus ladaniferous* (a good shrub, though per-

chance the rather fleeting nature of its flowers may cause it to be less popular in some gardens; be this as it may, a bush 5ft. to 6ft. high and 3½ft. across, is, when smothered in bloom, a picture not easily surpassed). An evergreen and deciduous *Rhododendron* must be in the list—the gorgeous heads of bloom of the former and the brilliant hued trusses of the *Azalea* make these shrubs among the most beautiful. *Azalea pontica* is excellent as a single specimen and still more showy when grouped, the same remarks applying to *Rhododendron fragrans*, *Eucryphia pinnatifolia*; *Rosa Hugonis* or *R. Moyesii*; *Spiraea ariæfolia* or *Aitchisoni*; *Exochorda macrantha*; *Cytisus Carlierii*, the lovely pale yellow Broom that flowers for quite two months from July; *Berberis stenophylla*. As only twelve are allowed to the dozen, *Magnolia*, *Olearia*, *Hydrangea*, *Philadelphus*, *Camellia*, *Deutzia*, *Viburnum* and *Genista* have had to be omitted from the final choice.—C. T., *Amphill Park Gardens*.

ACER GRISEUM?

IT seems almost presumption on my part to question the nomenclature of the plant sent to Vincent Square on October 17 by Mr. C. J. Lucas, under the name of *Acer griseum* and to which an award was given. I would venture to suggest, however, that the “absence of the peeling bark,” as specially noted in your description under New and Rare Plants, points to another species?

My plants of *Acer griseum*, now about 16ft. in height, commenced shedding their outer bark when quite immature, and are now never without the large hanging flakes of dark red peeling bark shewing the lighter skin underneath and which even extends to the side branches! I seem, too, to note other differences in the comparison with the spray photographed for THE GARDEN.

The leaves in the photograph appear somewhat larger and perhaps less toothed, while the seed keys are more acutely angled. I am strongly of opinion that if Mr. Lucas's Maple has not shed its bark now that it has reached the height of 18ft., it never intends to do so, and if this characteristic is essential, then another specific name must be found. In Mr. Bean's book (*Trees and Shrubs*, etc.), I

find under *Acer nikōense* the description of a species which seems entirely to fit Mr. Lucas's Maple.—H. W. GRIGG.

ASTER WILT.

IN his article on Michaelmas Daisies (page 539) Mr. Jacob refers to the "withering" which has of late years attacked these plants with disquieting frequency. As his remarks are likely to be misleading, and in view of the fact that he appears to be misinformed as to what "Wisley has said" and to misconstrue the absence of mention of the disease from "The Garden Doctor," it may be well to define the present position regarding the disease. When it originated, or where, we do not know. That it can be and is distributed by means of plants passing from one grower to another is certain. That the diseased condition of the plants follows the attack of a fungus in the lower part of the plant has been definitely proved at Long Ashton by Mr. Wiltshire and at Wisley by Mr. Dowson. That the source of fresh attacks upon healthy plants is soil infected by the spores of the fungus they have isolated and are studying is probable. Mr. Dowson has demonstrated that the fungus makes a poison that kills the foliage far away from the actual spot at which infection took place or to which the fungus has penetrated in the plant. He has also shewn that healthy tips taken from diseased plants may be rooted and will give perfectly healthy plants. It is therefore easy to secure healthy stock; it is probably impossible to cure a plant once affected; it is folly to plant in infected soil. So far our new knowledge takes us; but there is much more we want to know, and as it happens the discovery of these things would probably be of very far-reaching effect. They call for prolonged and tedious, and possibly costly, investigations; but they are well worth while, and the endowment of such research would be likely eventually to confer lasting benefit upon horticulture. We know (or believe) that environmental factors determine to a large extent the intensity of the disease, and probably its first incidence. The juxtaposition of fungus and plant are by no means the only factors involved, but the other factors have to be sorted out, and the influence of each tested individually and in combination with one another. We know how to kill the fungus in the soil, but we have no sure method of applying this knowledge to large areas outdoors except at vast cost. If we had this knowledge, we might be able to use it in many directions. As it is we are handicapped in our efforts to grow many plants healthily and well, whether they be for use or ornament, and when success crowns our efforts it is often merely empirical. We cannot ensure success in the future. Perhaps some public-spirited man of means will enable us to attempt the solution of these riddles and so to confer a lasting benefit upon horticulture!—F. J. CHITTENDEN.

THE CAUCASIAN SCABIOUS.

NOW that Messrs. Isaac House and Sons have shewn the public what can be done with *Scabiosa caucasica* I had hopes that this Queen of Hardy Flowers would be more generally grown by amateurs. They are, however, not likely to be encouraged if rash statements like those contained in your issue of October 21, page 525, are not contradicted. This Scabious is quite easily grown in a light, well drained loam and requires only (1) full sun, (2) to be kept dry in winter, (3) to be guarded against slugs. As for "auto-intoxication," I have grown them for twenty-five years on the same ground and have plants twelve years old shewing no signs of deterioration. They are easily propagated from seed or division in August or the spring (to divide in the autumn

I have long ago found certain failure). They like lime (I have found no other manure necessary) and are worthy of a place to themselves and not in the mixed border.—LANCASTRIAN.

["Lancastrian's" views on *Scabiosa caucasica* are interesting and go to shew the partiality of the plant for limestone or chalky soils, but it would be doing vendors of the plant a disservice to hold it up on most soils as a long-lived plant if left alone. Even on "Lancastrian's" own shewing a plant which needs to be "kept dry in winter" and to be "guarded against slugs" is not one for the careless gardener. Experience has convinced us that on a great variety of soils this Scabious may be kept only by annual division, preferably in very late summer or early autumn. The plant is, of course, easily renewed from seed, but one cannot rely on such plants to come true to type.—ED.]

WHITE MARTAGON LILIES.

THE Hon. Mrs. Cropper encloses photographs of white Martagon Lilies, part of a long border in her garden, in case one of them should be thought interesting to other readers. They receive no special culture.—Kendal.

The climate of the English Lakes is very

WHITE MARTAGON LILIES AT KENDAL.

favourable for many Lilies. It is not easy to see why Auratum Lilies should not succeed there as well as in the Isle of Arran.—ED.]

THE COLOUR OF ROSA MOYESII.

THE correspondence on "The Twelve Best Shrubs" discloses, I am pleased to see, that the merits of *Rosa Moyesii* are at last receiving recognition. Veitch's auction at Coombe Wood in 1914 no doubt partook of the nature of a "bargain sale"; nevertheless, I was surprised (and gratified!) when a dozen plants were knocked down to me for 7s. 6d.! I think there can be no doubt that the reason this Rose is so seldom seen in gardens is that some nurseriesmen are marketing a variety which is not the true *Moyesii* as originally distributed by Veitch (and Allgrove). I have seen at the shows a plant with all the characters of *Moyesii* except that the colour of the flower was a hideous combination of brown, red and yellow, suggesting a relationship with the Austrian Briar. The true colour is difficult to describe, being unlike that of any other flower known to me. "Brownish red," "blood red" are mis-descriptions suggesting the spurious variety I

have mentioned; "deep old rose pink" is the nearest I can get, suggestive of shades one sees in Chinese and Indian silks.—A. B. BRUCE.

A NEW RACE OF CHRYSANTHEMUMS.

THIS season the autumn rains are fairly abundant on the Riviera, and everything is green and growing, a great contrast to last year, when no rain fell till after winter had begun, so the prospects of the winter gardens are hopeful. The ground, however, is still dry when one digs down deeply, so it is to be hoped there will be a further fall while the temperature is fairly high. As usual, there are surprises to greet one. Many shrubs and flowers have succumbed to the long drought, while others seem all the better for the long rest imposed by it. Tea Roses have thoroughly enjoyed the heat and drought, and are most promising, but most Hybrid Teas, and especially the Pernetiana section, are barely alive and must be pulled up! Of the newer Roses Hadley, deep red, and Golden Emblem are the only two that have stood the drought. Mermaid is growing strongly and is shewing flower, so that seems an acquisition among climbers. There is one newcomer in the garden that is decidedly attractive.

Hitherto on this coast we have been so satisfied with the blaze of colour provided by *Salvias*, *Zinnias*, *Begonias*, French Marigolds and other well known autumn flowers that *Chrysanthemums* have been at a discount save for cut flower. Last year, however, Messrs. Vilmorin shewed some very dwarf single Japanese *Chrysanthemums* in Paris, and from the photographs taken I thought them very attractive. I had already seen the very dwarf double varieties that, blooming late on this coast, were useful about Christmas-tide, so I sent for a few cuttings to see what these new varieties were like. The first impressions are so favourable that I hope English gardeners will go to the Paris shows next month and satisfy them-

selves as to their worth. To an outsider these two or three varieties now in bloom give the effect of *Cinerarias* of strange colouring, so dwarf is their growth and so flat are the spreading heads of narrow-petalled daisies. For bedding purposes and for edgings they will be a real acquisition if they last long enough in flower. *Cinerarias* are so valuable in spring gardens on this coast that an autumn flower that resembles it in effect must be welcome to all who care for their autumn garden. If they succeed in England, they would make a delightful dwarf edging to the late Asters, and probably be of some use in pots, though I think their proper place is in the open border. The Orange trees here are more laden with fruit than I have seen for many years. Where properly watered and attended to they are a "sight," weighed down with their fruit just as the Apple trees have been in England. The Lemon trees are recovering from that terrible frost of nearly two years ago, but the drought has punished them more than the Oranges. The markets seem fuller of flowers than ever, but neither fruits nor vegetables are as fine as I have often seen them.—EDWARD H. WOODALL.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Winter Greens.—All plants which may be included under this heading have made an abundance of growth this season, rendering work between them somewhat difficult. Select a dry day and remove any weeds, and at the same time cut away all decayed or decaying leaves so that light and air can penetrate more easily.

Celeriac roots that have become sufficiently large should be lifted and, after trimming off the leaves, be removed to a cool store and have some sand placed about the roots. Any left in the ground can be trimmed up and be protected from frost by being moulded up with some soil.

French Beans.—Where a fairly liberal amount of pipe heat can be commanded a sowing of French Beans can be made in 7in. pots, placing about eight or nine seeds in each, reducing the number, after the strouger may be determined, to five. Grow the plants in a light position, maintaining at all times a little humidity in the atmosphere by the use of the syringe.

Seakale.—Introduce batches every few weeks into the mushroom-house or wherever similar conditions may be had. When lifting the crowns in readiness for forcing save the best of the thong-like roots to furnish plants for another season. For the present they may be tied into bundles and buried in sand away from wet and frost.

Salsafy and Scorzonera may both be lifted and stored in cool quarters to be drawn upon as required. Cut the foliage off, but leave fibrous roots alone until sending to kitchen.

The Flower Garden.

Planting Roses.—The various positions for the plants having been prepared as advised in the last issue of THE GARDEN planting should now be pushed ahead as rapidly as possible. Plant the bushes, etc., the same depth as practised by the firm supplying them, and make them firm by treading. Newly made beds or borders of Roses, which may look a little bare the first season, could be given a carpeting of Aubrietias, Violas or Nepeta in colour to suit the Roses, but should not be allowed to smother the latter.

Border Chrysanthemums.—When removing these plants as they pass out of flower be careful to save sufficient to provide stock another year. Place them in boxes of sandy soil fairly close together and keep the boxes in cold frames during the winter, which treatment will ensure plenty of good cuttings during the spring. Some of the best displays from border Chrysanthemums are obtained from plants where they are allowed to remain undisturbed the second year, and where this method is possible it is well worth carrying out.

Herbaceous Borders.—The planting of these has been fully dealt with in THE GARDEN, but where no such work or that of regrouping is necessary, it only remains to remove all decayed foliage, etc., when the flower-stems are quite dead. Where it can be arranged for, groups of Delphiniums, Lupins and all robust plants should be liberally mulched with rotten cow dung, as this will prove of great benefit to the plants next season, especially on light land.

The Hardy Fruit Garden.

Pruning.—Plenty of this work is now waiting to be done, and every advantage should be taken of favourable weather to push the job ahead. The amount of time necessary for the operation at this season is, naturally, influenced by the time spent upon the trees during the summer. Pruning may briefly be classed under two heads, *i.e.*, spur pruning as practised upon Apples and Pears and, on the other hand, the removal of the fruited branches and laying in fresh wood for fruiting as generally adopted for Peaches. It may be that in some instances this can be varied, and a good illustration is the Morello Cherry, which will respond either to spur treatment or otherwise. When pruning fully established trees on the spur method, great care should be exercised that the trees do not become too crowded with spurs. Trees on walls and other supports should be dealt with first.

Fruit Under Glass.

Early Peach-House.—Just when to start forcing is purely a matter of convenience to suit the requirements of the establishment, and can only be settled by those in charge, but, where there are several houses, early December is quite a suitable time to get one on the move slowly. Should

the necessary pruning have been done after the fruit was gathered, it only remains now thoroughly to cleanse the house and get the trees cleaned with an insecticide before again tying them into position. It may be that the border has been dealt with owing to root pruning, etc., but if not, having finished with house and trees, remove all loose surface soil, then lightly fork up the border, and give a good dressing of broken loam, rubble, wood-ash and a little bone manure, taking care that all is made very firm. A temperature of 45° is quite enough to start with.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Spring Cabbage.—Early planted lots should now have a little soil drawn up to them on either side of the rows. This not only steadies the plants, but also acts as a protection to the stems.

Celery.—The very latest batch should now be ready for a final moulding, which should be proceeded with immediately the weather is favourable.

Fruit Under Glass.

The Early Vinery.—The Vines in the early house should now be pruned and everything put in readiness for a start early in the new year. After the pruning has been finished the interior of the vinery should be thoroughly cleansed. Wash down all the woodwork and glass with hot water, adding a quantity of Bentley's Insecticide. The latter will assist in eradicating the numerous insect pests common to fruit-houses. Wash the rods with a solution of Gishurst Compound. We find this the most effective and reliable of the many washes recommended for the purpose. The surface of the border should be carefully removed till the roots are reached and a fresh dressing applied. This dressing should consist of good fibrous loam with a generous sprinkling of coarse wood-ashes. Add a 6in. potful of fine grade vine manure to each barrow-load of soil. Should the border be over-dry, sufficient water should be given to keep it in a fairly moist condition during the winter.

Late Vines.—Where bunches are still hanging on the rods they should be examined at short intervals and all decayed berries removed. A little heat in the pipes with careful ventilation will keep down damp.

The Hardy Fruit Garden.

Gooseberries and Currants.—Cuttings of these should now be formed of shoots about 12ins. long. Choose strong, short-jointed cuttings from the current season's growth, and rub off all but four or five of the top buds on the Gooseberry and Red and White Currant shoots, as these are best grown with clean stems. In the case of Black Currants the basal buds should be left, as it is desirable that they send out vigorous growths from the base of the plants. Make a clean cut through a joint and insert the cuttings in trenches 6ins. deep and 6ins. apart in the rows, adding some sharp sand to the bottom of the trench should the soil be heavy. A partly shaded spot is best, and firmness at the base is essential. Keep the rows at least 12ins. apart.

Pruning.—Where a lot of pruning has to be done a start may now be made among the Currants, thinning out all spent growths and encouraging the formation of strong young shoots.

The Shrubbery.

Planting Trees and Shrubs.—This is a popular time of the year as regards the planting of trees and shrubs and the thinning and transplanting of others that may require more space in the shrubbery. Crowded belts of mixed shrubs are not always desirable unless for a screen, so if the finer plants are to be seen at their best they should be planted sufficiently far apart to allow for their proper development. In sheltered parts the choice *Desfontainea spinosa* should not be neglected, as its presence gives much pleasure with its dark evergreen foliage and trumpet-shaped flowers of scarlet and gold. The late-berrying shrubs should also be considered, none giving more satisfaction in our Northern gardens than the well known *Cotoneaster frigida*. The less known *C. Franchetti* is also of much value, being more graceful in habit and being better balanced as a shrub than *C. frigida*. It also carries its berries well through the winter. An interesting contrast is the common

Snowberry (*Symphoricarpos racemosus*) planted in conjunction with the Spindle Tree (*Euonymus europæus*), both being beautiful when in fruit.

The Flower Garden.

Dahlias.—These have now been cut down by frost, so should be lifted and stored in a cool place for the winter. Do not over-clean the tubers when storing, as the adhering soil prevents undue shrivelling of the roots.

Summer - Flowering Chrysanthemums.—Although these stand quite well out of doors in certain districts, we find it best to lift the necessary quantity of roots for propagating purposes, packing the roots closely in cutting boxes and working plenty of leaf-mould and sand firmly round the stools. They may be kept in a cool frame during the winter, and if treated thus better facilities are offered for obtaining cuttings in spring.

Spring-Flowering Plants.—Now that the beds have been cleared of their summer occupants, no time should be lost in having the beds filled with the ever-popular spring-flowering plants. Wallflowers in variety, Polyanthus, Erysimums, double and single Arabis and Myosotis, with Sutton's Giant Daisies, all prove adaptable plants. The appearance of the beds may be considerably enhanced by the judicious planting of various Tulips or Hyacinths among the plants.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Cinerarias.—Unless it is possible to introduce a little heat in frames where these plants are growing, the latter should now be removed to a cool, airy house. So transferred they should, if possible, be stood on a cool moist bottom, as they abominate heat and drought. A dry atmosphere and too much fire heat is fatal to Cinerarias. Plenty of air should be admitted on all favourable occasions, a temperature of 40° to 45° being quite high enough for them. Where large specimens are required some of the most forward plants should have a shift into 8in. or 10in. pots; this of course applies specially to the intermediate and tall-growing stellata varieties. Such plants are valuable for furnishing beds in large conservatories. The dwarf varieties, which are suitable for the benches, can be grown quite well in 6in. or 7in. pots. These plants enjoy a light, rich compost, and some old mushroom bed manure is excellent for mixing with the potting compost. Cinerarias are very subject to attacks of aphid, but this can be guarded against by frequent fumigation. The leaf miner often proves troublesome, but it can generally be prevented by spraying with some nicotine compound.

Herbaceous Calceolarias.—The plants obtained from seed sown during August will now require to be potted off and the earlier batches will also require a shift into larger pots. These plants thrive best in a light, rich compost to which some old mushroom bed manure has been added. Calceolarias enjoy moist conditions and should be stood on a cool bottom. Except with the object of excluding frost the plants do not require to be subjected to any artificial heat. Fumigation is frequently necessary owing to attacks of green fly, which quickly ruin the foliage of the plants. Continue to root successional batches of the shrubby section, according to requirements, and pot off rooted cuttings of the earlier rooted plants. Large plants of *Calceolaria Burbridgei* are excellent for winter flowering and are valuable for furnishing beds in the conservatory. This variety is so useful that it is surprising it is not more generally grown.

Tropæolum tricolorum.—This plant should now be starting into growth and the shoots are best supported by sprays of hazel. Well grown specimens are very effective when in flower and to produce good specimens five or six tubers should be placed in a 5in. pot. They grow well in ordinary potting compost and require cool greenhouse treatment throughout all stages of their growth. Beyond the fact that they are subject to attacks of red spider, their cultivation presents no difficulty. Dry tubers can generally be purchased at this time, and it is not yet too late to obtain successful results. *Tropæolum azureum* is a beautiful blue-flowered species from Chili which succeeds under cool greenhouse treatment, but I doubt if it is at present in cultivation; if so, I should be pleased to hear of it. *T. Jarrattii* is also seldom seen now. All three species, when their foliage dies down, should be stored dry in a cool place until they start into growth again.

Azaleas of the indicum section that were forced early last season and in consequence finished their

growth early, will now be available for forcing again. Varieties with forward buds should be selected and introduced to a warm house, when they should flower in some three or four weeks time. The plants should be kept well syringed as they are very subject to attacks of thrips. These Azaleas are imported in enormous quantities from the Continent, where they are cultivated in beds. They should be potted up as soon as they are received, using sandy peat for this purpose. After potting they should be stood in cold frames where they can be kept close until established.

If they have become dry in transit they should be thoroughly soaked before potting, as once peat is dry it is very difficult to wet again, and if the balls are dry the plants will likely drop all their leaves and flower buds. Azaleas are very popular for decorative work of all sorts, and if successional batches are used they may be had in flower for several months. Some of the small-flowered varieties are very beautiful and can be successfully grown in small pots.

Royal Botanic Gardens, Kew.

J. CUTTS.

chapter on Perpetual-flowering Carnations is a brief one—rather too brief. Perhaps this will be amplified in future editions and more information given respecting the more up-to-date varieties. The Schizanthus has been much improved as regards strains during recent years, and the author has not omitted to include this plant and to devote a very useful and instructive chapter to its culture. Under the heading of Miscellaneous the author some gives brief cultural hints on Sweet Peas, Azaleas, *Deutzia gracilis*, Freesias, Narcissi and Tulips, East Lothian Stocks, Violets, etc. All amateur cultivators who wish to increase their winter supply of charming flowers should procure a copy of this booklet as soon as possible.—GEORGE GARNER.

VEGETABLES ALL THE YEAR ROUND

November and December operations.

WE have reached the season of sere and yellow and it is conceivable that the inexperienced grower of vegetables thinks that his duties for the present year have come to an end, but that is far from being the case; on the contrary, he has immediately in front of him the important task of laying the foundation for next season's crops. Success then, as a matter of fact, will depend very largely indeed on the manner in which the late autumn and early winter work is done and the man who merely apologises to the soil now will find himself very heavily penalised in comparison with the one who carries out every detail to the extreme limit of thoroughness.

THE CONCLUSION OF HARVEST

Those who were wise in their generation completed all harvesting by or before the end of October, for one thing because there could not possibly be any further advantage in leaving produce in the ground and for another thing because the weather of November is never to be relied upon for important, urgent work, especially where the land is heavy. There are, however, always procrastinators who persist in allowing their Potatoes, and often Beetroots and Carrots too, to remain until November, and if they could find an excuse, no matter how thin it might be, they would leave them still longer. Let it be most clearly understood that there is no excuse, not even a bad one, and also that further delay must inevitably lead to direct and perhaps very serious loss. With the exception of Parsnips, which are best lifted in weekly supplies, get any roots that may still be in the ground out and into store at once.

GROWING CROPS.

There are, of course, numerous plants in active growth and, speaking generally, they are in splendid condition and ought to provide valuable food for the house regularly until the spring Cabbages come in. Late Broccoli is certainly a source of worry in many cases, but where any real difficulty has presented itself in the past growers have usually safeguarded themselves by reducing the area to the lowest limit and having a few rows of perpetual or Spinach Beetroot, grown hardily from August-sown seed, as these never fail to give abundant supplies of succulent leaves which, if they are not quite equal in flavour to some other vegetables, are infinitely better than nothing at all. The one duty associated with this group of plants is to hoe frequently to keep the soil open and the weeds down, but stringently to avoid that or other work entailing actual treading on the soil when it is wet.

PROFITABLE LABOUR.

Every opportunity must be grasped to push forward soil working during these two months, especially November, because strenuous labour now will always prove highly profitable in the ensuing season. The ground is opened up to

varying depths to admit air, rain and frost, each of which plays a part of paramount importance, and insect eating birds are able to proceed with their useful tasks more easily and successfully. It is, of course, for the individual cultivator to decide whether he will dig, bastard trench or trench his soil, but no one should be content with the depth of single digging when there is a greater cultivable depth at command on the one hand and no one should go to the length of trenching unless he is quite certain that the subsoil is sweet on the other hand; the intermediate course, called bastard, false or mock trenching, in which the subsoil is perfectly opened up but retained wholly in its original position is wisest in all instances of doubt and when it is done thoroughly the lower strata are sweetened by aeration and in due course trenching, undoubtedly the finest form of soil working can be done in the certain knowledge that it will be generously repaid. Whatever the system decided upon, let the surface remain as rough as possible, because this exposes a greater area to the action of the weather, and leads, consequently, to greater good. Manure, which is almost invariably best incorporated with the second spit, can be used now on medium to strong soils, but on very light, sandy land it is frequently preferable to leave it until spring, say till February. W. H. LODGE.

BOOKS

Winter Flowers.—The author of the handy, compact little booklet* on winter flowers is evidently well versed in the cultivation of the various kinds of flowering plants he has selected for his object, namely, the encouragement of amateurs who possess small greenhouses to fill them with useful and interesting plants during the dull days of winter. He has not used more words than are absolutely necessary to convey his meaning in a straightforward manner. Amateur cultivators will not find any difficulty in carrying out the practical instructions given. The selection of the plants is, of course, not an exhaustive one, but it includes those that will afford a good supply of cut flowers and those, too, that will furnish the stages with handsome, attractive pot plants, such as Cyclamen, Primula, Cineraria, Calceolaria, Schizanthus, etc. Those to yield cut flowers include Chrysanthemums and Tree Carnations. All the plants dealt with may be economically grown, as they do not require much artificial heat to bring them to perfection. The author rightly devotes some space to "Hints on Lifting Chrysanthemums" in addition to their treatment in pots. Lists of suitable varieties are given. The

For the Gardening Beginner.—Of the books for the instruction of the new-comer to the gardening fold there is no end. It was in expectation of some very pleasurable reading that we opened a newly issued book printed in large, clear type and written by those well known and deservedly respected horticulturists, Messrs. Horace J. and Walter P. Wright.† Yet now, after perusing more than half of it, the writer has pushed it impatiently away in disgust. The matter of the book bears every indication of its having been written before the war—probably several years prior to 1914. What service to *anyone* is a work so out of date as to omit Hugh Dickson from a list of Hybrid Perpetual Roses, Lady Hillingdon from the Tea section and General McArthur from the "H.T.'s"? The lists of climbing and Wichuraiana Roses are equally antiquated. Dorothy Perkins, for instance, is included under Climbers. Under Wichuraiana appear only Albéric Barbier and Gardenia. The magnificent American Pillar is nowhere mentioned, nor are such sorts as Elise Robichon, Excelsa, Dorothy Dennison, Jersey Beauty, etc., to be found. The list of Michaelmas Daisies is equally out of date. What can we think of this? "There are many varieties, of which Bessarabicus, Framfieldii and Riverslea (forms of the species *Amellus*), Mrs. Raynor and Wm. Bowman (forms of the species *Novi-Angliæ*)"—the spelling is as given—"and *ericoides* are a few of the best. *Alpina* and *Novi-Belgii* are also good." The italics are the reviewer's! To think of Michaelmas Daisies without Climax and some others of the *Novi-Belgii* is worse than picturing Hamlet without the Prince!

The article on Gladioli is no more up to date. Hybridisation is spoken of in the past tense, and there is not a word about the all-conquering *primulinus* hybrids, let alone the new "ruffled" forms. A fairly long list of Violas does not include Moseley Perfection! Again, "At the time of writing, the popularity of the Pæony Dahlias is rather a matter of promise than of fact. So far only a few varieties have appeared." Show and Fancy Dahlias are differentiated, though the National Dahlia Society has amalgamated them, and the three Star Dahlias mentioned are Jupiter, Mars and Saturn! Even the list of Sweet Peas is equally out of date. Further, the only mention of *Lupinus polyphyllus* describes it as blue, but "There are several varieties, including a white, a purple and a yellow (Somerset)"—no mention of the pink sorts at all!

The titles of some of the chapters are not too happy, e.g. that on "Hardy Herbaceous Plants," which includes such things as China Asters and Phlox Drummondii. Of these latter it is stated "Named varieties of annual Phlox are not offered," which will be news to most people!

SOME BEAUTIFUL ANEMONES

NO one could call the Anemone a popular flower and yet it undoubtedly comprises some species and varieties as beautiful as anything that Nature can shew and in its whole range, so far as we know it at present, there is nothing ugly and very little that is not really beautiful. The colour range is very extensive and includes brilliant reds (*AA. fulgens* and *coronaria*), bright blues (*AA. apennina* and *blanda*), clear yellows (*AA. ranunculoides* and *palmata*), and a great variety of soft shades of purple, pink and yellow, besides wonderful crystal whites. Some of the alpine species are perhaps a little difficult, at any rate they need special treatment, and some species and strains need some winter protection, but there are many to which neither qualification at all applies. It is therefore a matter for speculation why the Anemone is not more highly esteemed by gardeners generally. Perhaps it is awaiting its turn. It may be that the day will come when this flower will have a society to further its interest. There are many who think it far worthier of such assistance and distinction than the rather coarse and only half-hardy, if very useful, *Dahlia*.

The brilliantly coloured *St. Brigid Anemones* and their relatives and progenitors, *AA. fulgens* and *coronaria*, are worthy of more detailed consideration than can be afforded them here. The beautiful and useful Japanese Anemone in its many charming varieties is generally known and cultivated and it must suffice now to call attention to the merits of two varieties which are not so widely grown as, according to their merits, they certainly deserve to be. These are *Géante des Blanches*, the magnificent and substantial pure white which should entirely supersede *Honorine Joubert*, and *cristata*, with soft rose flowers and pretty divided rather ferny foliage.

The *Hepaticas* alone, with their welcome blossom in early spring, should make the Anemone family an honoured one in gardens. The original and typical single blue form is undoubtedly the best, but the albino and rosy varieties are also welcome. The double blue is very rare and correspondingly dear, but has no special garden value. The double white, too, is uncommon,

but the double rose is very plentiful and cheap and, being a shade deeper in colour than the single rose form and more lasting, is worth having. *A. angulosa*, however, is the finest of the *Hepaticas*, the flowers being larger and the habit of the plant more lax than in *A. Hepatica*. The typical plant is a glorious bright blue, but there are several colour forms in commerce and a rather uncommon pure white one.

It is doubtful if any species is really much more beautiful than our native *Wood Anemone*, *A. nemorosa* which, as generally seen, is a pure, if partially transparent white with, of course, beautiful clusters of golden stamens. In the west,

however, forms with blue coloration abound, of which probably the finest is *A. n. Allenii*, though many prefer the more fragile looking, rather opalescent *Robinsoniana*, in which most of the colouring is on the exterior and shines through. Though so fragile looking this is a good "doer" and, in a nice leafy compost will increase rapidly, even in the open rock garden. There is the inevitable double form and a much more beautiful one called *bracteata* which in any other flower would be called "anemone-flowered."

Of the *nemorosa* kindred, *A. trifolia* is an alpine, more robust in appearance and more solid of flower. Like *A. nemorosa*, it has a tendency to produce blue-flowered forms but, white or blue, it is always lovely and, under similar conditions to the *Wood Anemone*, easy. *A. nikkoensis* from Japan is, except for slightly more cut foliage, almost identical with *A. nemorosa*. *A. ranunculoides* is near akin though the more cup-shaped and smaller blossoms are practically buttercup yellow. Small clumps with few flower heads are not attractive, but a little drift, whether in semi-woodland or in the rock garden, is pleasing enough. From Siberia comes a very similar plant called *A. cœrulea*, though the blue appears never to be more pronounced than that of *A. nemorosa Robinsoniana*. Forms with more pink than blue are common.

A. alpina and its variety *sulphurea* adorn vast stretches of the European Alps. Both species and variety are exceedingly variable and it is very necessary to look out for good types for our gardens. This species has huge woody rootstocks and needs a deep, well cultivated soil quite in the open. A light, moderately fertile loam suits it best, which must be really well drained. The best forms of *A. alpina* are larger flowered than the sulphur form and in their snowy purity magnificent, but this latter is entirely worthy and so distinct as almost to deserve specific rank. *A. occidentalis*, the corresponding form from the New World, is smaller in all its parts, rather starrer of flower and with much more finely divided foliage. It requires similar cultural conditions.

The clear blue stars of *A. apennina* are one of the joys of the spring garden. Easily established in any light

A CHOICE WHITE ANEMONE, *A. RUPICOLA*.

ANEMONE ALPINA SULPHUREA ON THE MEIDEN ALPS.

THE EXCEEDINGLY GRACEFUL ANEMONE NARCISSIFLORA

A COLONY OF ANEMONE NEMOROSA ALLENII.

rather leaf-mouldy soil in full or partial shade, it is one of the "indispensables." *A. blanda* has usually the same clear blue flowers, but is smaller habited and less leafy. Of the two species it is the less effective, but has the more than counterbalancing advantage of early flowering. The scanty foliage quickly withers after flowering and it may be used, with or without a carpet of Stonecrop or other light carpeter, to fringe a shrubbery. It succeeds in open woodland, however, and is admirable there, though it flowers most freely and increases (from seed) most readily on the southern fringe where the sun can penetrate to ripen the tubers. There are soft pink and rich purple forms and, perhaps, most beautiful of all, the variety *scythica*, of which the flowers are blue without, white within.

The Pasque Flower, *A. Pulsatilla*, may be taken as typical of a very quaint and beautiful section of the family. It is often found as a wilding in Britain, but is not truly indigenous, having probably been introduced by the Romans, who used it as a dye. As raised from seed the Pasque Flower varies somewhat in hue, but is almost invariably some rich but rather sombre shade of purple. The opening flowers are held erect, but as the stems elongate they become more or less pendent. The slowly unfurling, much divided leaves are one of the plant's chief charms at blossom time, for they are a delightful silvery grey in colour and wonderfully silky in texture. There is a pure white form called White Swan and a clear shell-pink one called Mrs. Van der Elst. The plant, usually or, at least, often offered as *Pulsatilla alba*, is not a pure white, nor very pleasing. *A. Pulsatilla* is quite easy to grow in any well drained soil with a good lime content. It is apt to become coarse and weedy in loose or over-rich soils.

Closely related is *A. Halleri*. The foliage of this species is also grey and silky, but not at all finely divided and the flowers are throughout held erect. The flowers are violet purple within and heavily hung with "silk" without. This, perhaps the most beautiful of the *Pulsatilla* clan which have found their way into our gardens is also a European alpine, but unlike that species it is calcifuge. A good depth of sweet, not over rich loam in full sun meets its requirements.

Three other species of the *Pulsatilla* group sometimes seen in gardens are *AA. pratensis*, *montana* and *patens*. *Pratensis* too often masquerades in gardens as *Pulsatilla*, to which, in fact, it is much inferior. The foliage is similar, but the flowers are duller in colour, *never* held erect, even when first open, and narrow bell shaped, whereas in *Pulsatilla* they are flat, cup-shaped. *A. montana* is a more interesting plant, but rare in gardens. The flowers are ruddy purple—sometimes very dark—and the foliage dark green, not grey. The blossoms are, in shape, somewhat like those of *pratensis*, but are borne on taller stalks. With *Anemone patens* the foliage does not commence to unfurl until after the blossoms have expanded. The very distinct much cut, but, on the whole, rather rounded foliage, is smooth and green above, but silky beneath.

In *A. narcissiflora* we come to an alpine of a totally different type, and distinct with grace and loveliness. The blossoms are creamy, often with a purplish stain on the backs of the petals and the plant is not inaptly named, for something in the pose of the loosely clustered flowers reminds one of some of the polyanthus *Narcissi*; moreover, at a little distance, the clustered stamens suggest the *Narcissus* cup. It grows about a foot tall and like many other alpine seems to have an objection to isolation. It is much happier interplanted and hedged about with other plants of, preferably, dwarfer habit—small Ferns answer excellently.

Similar conditions suit *A. sylvestris*, though many find this easier to grow. Indeed, given fairly rich

light loam and a tolerably moist, but not boggy, root run, it will, like *A. japonica*, run about until it is almost a nuisance. The flowers, though smaller, are reminiscent of those of the Japanese Anemone, but carried on naked stems 8 ins. to 10 ins. tall. *Anemone rupicola* from the Himalaya is more or less intermediate between *AA. sylvestris* and *japonica*.

A. baldensis is a true alpine from the Southern Alps, including the Dolomites, and is always found at very considerable elevations. Farrer recommends to grow this white-flowered gem, which

is sparse habited and spreads by underground wires, in "a very earthy moraine with a few large coarse blocks buried in it and water flowing below," but given a light, rather stony soil and the company of other dwarf plants, it has always succeeded, if not exactly flourished, with the writer.

With *A. palmata* we come to the end of the species to which it is desired to call attention. This is undoubtedly the best of the yellow species and not at all difficult of culture in the sunny rock garden. It likes a deep soil containing a fair amount of humus and sharp drainage.

HEATHS AND OTHER SHRUBS FOR UNDERGROWTH

ANY light woodland loam, free from lime, is a suitable medium for the growing of a considerable number of lowly shrubs which, in addition to their own individual beauty and interest, are useful for covering the ground beneath trees and

fine-leaved foliage in a peculiarly vivid moss green which is distinctive. Among such Heaths as the above, various *Cotoneasters* as, for example, *CC. microphylla* and *congesta* may be planted with most charming results, even on the flat. In addition to these species one may mention the

Pachystima Myrsinites and *P. Canbyi*, hardy American evergreens of about 1 ft., with box-like leaves, are uncommon and interesting shrublets for the rather more open spaces. *Pachyandra terminalis*, from Japan, with its variegated form, may also be planted in shade that is not too dense, and the American *P. procumbens* will do in similar conditions. Both of these are quite dwarf foliage plants, but the latter, being sub-evergreen, is the less attractive. The Sand Myrtle, *Leiophyllum buxifolium*, is another little evergreen shrub in character with the above, but in addition to its small but numerous dark green, glossy leaves it bears a multitude of tiny white flowers which are preceded by vivid pink buds. This is quite easy in average cool loam where the shade is not too heavy, but the allied *Ledums*, of which there are several good kinds, do not seem to prosper here save where moister and more peaty conditions are provided. This also applies to our native *Andromeda polifolia*, which, however, is a low, spreading shrub well worthy of the attention of those who can give it the necessary dampness and a vegetable soil.

The *Euonymus* genus affords several dwarf species of exceptional merit for the purpose in view, both evergreen and deciduous, and the fruits of some of these are well known for their brilliant colours. Many of the lesser *Veronicas*, often grown in the rock garden, may also be included here, more especially those whose foliage is their chief attraction. The partial screen against frost provided by the branches of deciduous trees is of no small assistance in preserving through the winter such of these *Veronicas* as may be too tender to stand more exposed conditions. A selection should include *VV. lycopodioides*, *loganioides*, *cupressoides*, *Hectori*, *carosula*, *edinensis* and *decumbens*. For breaking the monotony, or wherever something taller is desirable, *Veronica Traversii* is excellent.

The *Vacciniums* also comprise several species which are of lowly stature and by nature eminently adapted for life beneath tall woodland trees in any lime-free loam. *VV. buxifolium* (*Gaylussacia brachycera*), *pennsylvanicum*, *Vitis-Idæa*, *macrocarpum* (*Oxycooccus macrocarpus*) and *canadense* are among the best, and some of these are not only pretty in flower and fruit but they assume fine autumn tints.

Ruscus aculeatus (Butcher's Broom) will thrive in the densest shade, and then there is the less rigid and generally more pleasing Alexandrian Laurel, *Ruscus racemosus*, which prefers a rather more open situation. Though both of these delight in a calcareous soil, they will do quite well in lime-free loam. The familiar Rose of Sharon, *Hypericum calycinum*, is one of the handsomest of woodland flowering shrubs we possess, but, one need hardly add, it must be used with caution owing to its ramping nature. *H. Moserianum* is equally good, much safer and its variegated form is very distinct. *Hymenanthra crassifolia* is a low-growing, shrubby New Zealand species, hardier than most plants from that country, and one that may be planted with confidence in any thin woodland. It may be grouped with good effect with such shrubs as *Corokesas*, also from New Zealand, with their pretty leaf tints and yellow fruits, provided the shade is not too heavy. Nor can one pass over the merits of that diminutive Holly, *Ilex crenata*, of which there are one or two attractive varieties. The best forms of *Berberis Aquifolium* (Oregon Grape) are admirable for woodland, and we have found *B. Wallichianum* first-rate for semi-shade. *B. Bealii*, since it flowers in mid-winter, appreciates the shelter afforded by tall deciduous trees, and other members of this charming race suitable for such planting will occur to the reader who scans the trade lists. A. T. J.

VERONICA TRAVERSII IN A WOODLAND GARDEN.

caller shrubs and thus enhancing the general effect.

Many of the Heaths are admirable for such conditions. If they do not bloom quite so abundantly as with full exposure, they give more colour than most shade plants, and that at seasons when flowers are comparatively few. *Erica cinerea*, in a robust form like *rosea*, or even the typical wild species, is one of the best of Heaths for fairly open woodland, and one that will blossom freely over a long period in summer. Another first-rate member of this genus is *E. carnea*. This species flowers from January to May, and we have plantations in the shadow of Oaks which give as fine a display of colour as those fully exposed. *E. darleyensis*, though it will make a dense bottom growth of a deeper and more pleasing shade of green than the foregoing, does not bloom quite so freely as it does in full light. Then there is the prostrate form of *E. scoparia* (var. *pumila*) which will form a thick-set, low cushion of

deciduous *C. horizontalis* and its smaller "edition" *C. adpressa*.

Most of the *Gaultherias* are also suitable for woodland. Among these *G. trichophylla*, a little creeping species with deep green leaves and pink flowers which produces pale blue berries as large as a robin's egg, is one of the most delightful. *G. nummularioides* is another excellent species, and the white-berried and more shrubby *G. pyrolaefolia* should always be given a place. *G. procumbens*, which will carry its bright crimson fruits all winter, is another deservedly popular kind, and there are several others, including *G. Shallon*, whose normal height of 4 ft. is usually much less in land not naturally moist. Though generally listed among the peat plants, all these *Gaultherias* will do in a lime-free loam which does not get too dry in summer. An occasional top-dressing of leaf-mould or half-decayed fir needles in spring is beneficial, and some of this should be incorporated with such soil when planting.

THE NEW SWEET PEAS

THE Sweet Pea is still a popular flower. The leading raisers are busy improving and reselecting stocks of the favourite standard varieties as well as introducing new colours. At the same time they are losing little, if any, of the charm that characterises the flower from a decorative standpoint, its gracefulness and scent. A bunch of freshly gathered modern Sweet Peas is sufficiently fragrant to diffuse a delicate perfume indoors, and when one walks down the rows on a warm, sunny day the presence of the Queen of Annuals is quite evident. There are critics who would have us believe that no modern lavender Sweet Pea can compare with the old Lady Grisel Hamilton, that Dorothy Eckford or Nora Unwin are still unsurpassed as whites, or that Moonstone or Mother o' Pearl have not yet been equalled in their respective colours, but when these are grown side by side with such fine new varieties as Powerscourt and Elsie Dene, Austin Frederick Improved or any of the modern frilled Sweet Pea can compare with the old Lady Grisel Hamilton, that Dorothy Eckford, Moonstone and Mother o' Pearl have had their day—it is the age of the super-Spencer type.

I do not think that the up-to-date grower will have much cause for complaint if he tries a selection of the undermentioned new Sweet Peas. Most of them I know well, many of them I have tried for the past two seasons, the hot, dry summer of 1921 and the past year when the weather was the reverse.

The raiser's name is indicated in parentheses after each variety.

Advance (E. W. King and Co.).—A rich shade of rosy pink on a white ground. For many years Mr. Burt has been trying to obtain an outstanding variety in this popular colour, and this novelty is the greatest advance he has yet made, hence the name. The flowers are beautifully formed, with a great proportion of double and triple standards, and in the height of the season borne mostly in fours. I have found this variety most reliable in all kinds of weather. It is one of the best of the novelties.

Artistry (Bolton and Son).—This variety is starred as the best in the Fancy Section in the new Classification List of the National Sweet Pea Society just issued. It has very similar colouring to the old variety Princess Mary—shades of blue and lavender pink. There is an opal sheen in the standard, and when well grown this art shade is very pronounced and beautiful. It is a really vigorous grower and gives an abundance of four-flowered sprays on long stems.

Benbow (Damerum).—A brilliant shade of carmine which produces fine flowers with very long stems. It will be a rival to Renown and Mascott's Ingman.

Cynthia (J. Stevenson).—Mr. Stevenson says of this novelty, "The largest pale lavender without a doubt." It is an improvement on his variety Faith, both in size and colour, and is very strongly perfumed.

Diana (J. Stevenson).—A rich lavender-coloured Sweet Pea which Mr. Stevenson tells me is more frilled and rather deeper than Austin Frederick Improved, a variety that is very popular in the North. Diana is of very vigorous constitution, and it beats its famous rival it should prove one of the raiser's masterpieces.

Elsie Dene (Bolton and Son).—When I saw this growing in the seed rows at Mr. Bolton's it

struck me as being the finest of the pure lavender blues. Under glass it is a soft shade of lavender, but out of doors the colour is cleaner and more distinct. It is a novelty of super-excellence, and one that is certain to become very popular.

Faerie Queen (Alex. Dickson and Sons).—When grown under glass or for garden decoration this Sweet Pea is very beautiful. It is a lovely shade of salmon pink on a cream ground with a ray of apricot salmon across the centre, the blend of colour being quite unique.

Improved Elegance (Woodcock).—A superb stock of the well known variety with a richer tone and the same perfect placing of the blooms. Mr. Woodcock sent me blooms of this during the summer, and I was much impressed with it. He tells me that it has been in great demand and the stock is nearly exhausted.

Improved Jean Ireland (Woodcock).—This was to have been sent out as Sylvia, but the colour is practically identical with the old favourite, so that it was decided to retain the popular name. Mr. Woodcock has thus given the start in a commendable attempt to prevent multiplicity of names. It is having an enormous run, and Mr. Woodcock tells me that almost every order includes it. I have grown it this year, and can bear out the raiser's claim that it is a rampant grower, with huge stems and an abundance of fours.

Kenneth (Dobbie and Co.).—Those who are familiar with the very frilled type of Sweet Pea that Messrs. Dobbie and Co. have made famous will be pleased with this novelty, which is a rich shade of rose on a cream ground and which keeps its colour well in water. It is short-jointed and makes an ideal flower for the exhibitor or for culture under glass. It has done well with me this year.

May Cowdy (Unwin).—May Unwin had great length of stem, and Edward Cowdy that rich, almost dazzling flame colour, especially in the standard. May Cowdy is a fictitious name that helps to show that the novelty combines the best points of each of the others. It should be a great favourite with Irish growers, who seem to get the best out of these orange-scarlet shades.

Mignonne (E. W. King and Co.).—A pretty name for an equally pretty Pea. I have tried it for two seasons and have found it most beautiful. It is the softest shade of pale cerise on a cream ground, rather a delicate grower and not quite sunproof, but well worth a little extra care in cultivation. Under lamplight the colour is exquisite.

Mrs. H. Richards (Unwin).—This is a very pretty decorative variety with a salmon rose flush over a white ground. The deepest shade of colour is in the wings and the centre of the standard. It is a vigorous grower with well placed blooms on long stems.

Mrs. Norman Lambert (Woodcock).—The most distinct of the novelties, a rich blood crimson not unlike the colour of the dark red Roses. It is quite sunproof; in fact, it simply revelled in the hot summer of 1921. A patch of this variety in full bloom is a most brilliant sight and its unique shade instantly arrests attention. It is a vigorous grower with plenty of fours on long stems. Like Mr. Woodcock's other novelties, it is in great demand.

Mrs. Stirling Stent (Damerum).—A rich shade of salmon rose and one of the most pleasing colours for culture under glass.

Poppy (J. Stevenson).—A very vivid orange red that is absolutely sunproof. In late autumn Mr. Stevenson had plants of this variety 10ft. high and 3ft. through the rows all ablaze with bloom.

Powerscourt (Alex. Dickson and Sons).—Mr. G. T. Dickson says that this is the finest pure lavender extant and, judging from the magnificent blooms he sent me in late August, his opinion will not be far wrong. They were nearly perfection. Purity of colour, refinement and length of stem were the chief characteristics, and every spray was a four. It is one of the finest of modern introductions—an outstanding novelty.

Ringdove (Dobbie and Co.).—A lovely cream pink counterpart of Kenneth, with the same heavy frilling in the standard and a similar habit. A great Sweet Pea grower has said that this variety in the hands of an expert would be capable of producing flowers that would be unbeatable for quality.

Rosemary (E. W. King and Co.).—A very distinct Sweet Pea—rich carmine pink overlaid on a white ground—that, owing to its very vigorous habit and great length of stem, is very easy to grow. It makes a brilliant bit of colour in the rows.

Royal Flame (Bolton and Son).—The most striking colour yet evolved, and when I saw it growing under glass at Birdbrook it was at least 10ft. high and literally smothered with dazzling blooms. All who grow Sweet Peas in the greenhouse should not fail to try it. Out of doors it should be shaded.

Royal Cherry (Alex. Dickson and Sons).—Another very beautiful new colour, bright salmon cerise which intensifies towards the edges of the standard, afterwards changing to deep rose. It needs to be well grown to be seen at its best.

Shamrock (Ireland and Hitchcock).—A rosy mauve with the vigour of R. F. Felton. The colour brightens after the flowers have been kept in water.

Sheila (Damerum).—Another addition to the pale cream pinks. It is highly recommended for exhibition work.

The Sultan (E. W. King and Co.).—The best of the very dark Sweet Peas. It is a shining black maroon. Of similar habit to Rosemary, and I find it as easy to grow as this variety. It will make a very telling vase for exhibition.

Viscountess Lascelles (Damerum).—A pale lavender with a very frilled standard that was much admired at the last Chelsea Show.

Wild Rose (J. Stevenson).—Mr. Stevenson tells me that everyone who has seen this novelty wants it. It is a very vigorous grower, and the colour is a soft shade of old rose with a flush of orange in the standard.

Wonderful (Bolton and Son).—When I first saw this variety two years ago I was very much impressed with its wonderful colouring, and suggested to Mr. Bolton that it could have no better name than the adjective which so aptly describes it. To see it growing in the long rows at Mr. Bolton's home gives a true impression of its striking colour, and it may be described as a deeper Royal Scot. I have found it as sunproof as that famous variety.

A dozen clumps of the following novelties would look very effective in this order: Wonderful, Advance, Poppy, Powerscourt, Kenneth, Improved Jean Ireland, Mrs. Norman Lambert, Elsie Dene, The Sultan, Mrs. H. Richards, Shamrock and Benbow. It would be a representation of the latest creations of the leading raisers of this very useful, almost indispensable, annual.

NORMAN LAMBERT.

TREE AND SHRUB GARDEN

PENDULOUS OR WEeping TREES

TREES of weeping or pendulous habit can be most effectively planted in the pleasure grounds and park. They are perhaps seen to best advantage on closely shaven lawns. The more or less formal outline of weeping trees can be used effectively, too, in courtyards and terrace gardens. With a little training some weeping trees make excellent arbours in summer. The best for this purpose are the pendulous forms of the common Ash, of the Beech, and of the Scotch and Feathered Elms. In the park, protection against animals is necessary, unless the trees are grafted or trained to a considerable height in the early stages of growth. Shady arbours by the waterside are refreshingly cool and delightful in summer. The best trees for this purpose are the pendulous Willows, Alder and Aspens.

There are two distinct types of pendulous or "weeping" branches, the first being of more or less prostrate habit of growth and requiring constant training to produce specimen trees. This type is represented by *Ulmus montana* var. *pendula* and *Fraxinus excelsior* var. *pendula*. The second type comprises trees which naturally grow more or less upright but have distinctly pendulous branchlets, as illustrated by *Salix babylonica* and *Taxus baccata* var. *Dovastoni*.

While a good number of the second group can be grown on their own roots, by far the best results with the first group are secured by grafting on the straight or type species usually fairly high up to give the tree a good start. Until the desired height is attained it is necessary to keep the leader or leaders tied to a central stake. To obtain the large arbour (umbrella) like growth with the clean central trunk the pendulous graft is worked at a height of 8ft., 10ft. or more. The spread of the branches is gradually trained outwards. In course of time supports in the form of props are often necessary to keep the branches off the ground. If the tree is used as an arbour, the props must necessarily be 6ft. or 8ft. long.

I have in mind a beautiful specimen Weeping Beech, with at least twenty props beneath, under which it would not be difficult to accommodate twenty-five to thirty people to tea.

Taken botanically, in alphabetical order, the most important pendulous trees include:

ACER DASYCARPUM PENDULUM.—This form of the Silver Maple has pendulous branches. It no doubt originated as a seedling, being an extremely graceful tree requiring only normal training.

ALNUS INCANA PENDULA.—A Weeping Alder of which there is said to be a specimen at Elvaston Castle about 100ft. high.

BETULA YOUNGH.—This Birch has more or less pendulous branchlets. Young's Weeping Birch is a very distinct and attractive tree.

CRATAEGUS MONOGYNA PENDULA.—The Weeping Hawthorn is a most beautiful tree when in flower, and particularly valuable for small gardens.

FAGUS SYLVATICA PENDULA.—The Weeping Beech is one of the widest spreading and best known trees of pendulous habit. *F. s. purpurea pendula* is a Weeping Purple Beech.

FRAXINUS ANGUSTIFOLIA PENDULA and *F. EXCELSIOR PENDULA* are distinct and ornamental.

A NOBLE LIME, *TILIA PETIOLARIS*.

The last named can be very effectively trained to form a "living" summer-house or arbour. At Elvaston Castle, Derby, there is a famous Weeping Ash 98ft. high. It was illustrated in *THE GARDEN*, Vol. LXVIII, page 400.

ILEX AQUIFOLIUM PENDULA.—The Weeping Holly is an attractive evergreen, forming a beautiful lawn specimen when worked high up and carefully trained. There are also silver (*argentea pendula*) and golden (*aurea pendula*) forms.

JUGLANS REGIA PENDULA has rigid branches which must be worked high up to be effective.

MORUS ALBA PENDULA.—The Weeping white Mulberry is a very elegant tree when well grown. It is a most persistent "weeper," requiring unending attention to form the framework of a specimen tree.

POPULUS TREMULA PENDULA and *P. TREMULOIDES PENDULA*.—The Weeping Aspens form distinct and attractive trees. The former is more rigid in outline and has the more attractive (male) catkins. The latter is a female and has longer, more slender twigs.

PRUNUS PENDULA.—The Japanese Rosebud Cherry is said to be a tall tree in Japan 50ft. high, but it attains the dimensions of only a small tree in British gardens. It is attractive when covered with delicate pink blossoms in spring, but, unfortunately, these open rather early and, together with the young growths, are frequently damaged by frosts. One of the best weepers of the Plum family is the Weeping St. Lucie Cherry, *Prunus Mahaleb pendula*.

QUERCUS PEDUNCULATA PENDULA.—The Weeping Oak is not so well known as the pendulous forms of the Ash, Elm and Beech, probably because it is slower in growth.

THE WEeping WYCH ELM, *ULMUS MONTANA PENDULA*.

SALIX BABYLONICA.—The Weeping Willow is the best known and possibly the most beautiful of all trees with pendulous-branches, and a very attractive waterside tree. *S. VITELLINA*, *S. CAPREA PENDULA*, the Weeping "Palm" or Kilmarnock Willow, and *S. PURPUREA PENDULA* are all desirable trees for moist soils.

TAXUS BACCATA DOVASTONI.—The main stem of this Yew is upright, the branches more or less horizontal and the branchlets drooping. This is a female tree and one of the handsomest of all Yews. [We were under the impression that this is a male form.—ED.]

TILIA PETIOLARIS (*T. americana pendula* of some gardens) is a tall tree with pendulous branches.

The undersides of the leaves, which are white, shew when swaying in the breeze, hence the name Pendent Silver Lime. One of the most beautiful Limes in foliage and flower.

ULMUS GLABRA (NITENS) PENDULA.—The Weeping Smooth-leaved Elm and *U. MONTANA PENDULA*, the Weeping Scotch or Wych Elm, are two well known pendulous trees, especially the latter with its stiffly pendulous growth.

There are also pendulous-branched forms of numerous conifers, notably *Cedrus atlantica pendula*, *C. Deodara pendula* and *C. D. robusta*, *Cupressus Lawsoniana pendula*, *C. nootkatensis pendula*, *Sequoia gigantea pendula*, and *Tsuga canadensis pendula* and *T. c. Sargentii*. A. O.

SHRUBS HARDY IN YORKSHIRE

MY experiences of three of the New Zealand Olearias alluded to in the interesting and suggestive contribution to THE GARDEN of October 7 (page 500), in this cold north-east corner of Yorkshire, may be of sufficient interest to put on record. *O. stellulata* stands very well, giving freely of its pretty white daisy flowers every summer; cold frosty winds sometimes cut the foliage back, especially in the late spring, but when this happens it usually recovers and flowers a little later. *O. nummularifolia* has taken very little harm up to now, but grows very slowly and the flowers are not nearly so showy as *O. stellulata*, and the foliage is much

holly-like leaves and its fine clustered heads of white daisy flowers.

The whole of the Rock Roses (*Cistus*) established here withstood all recent winters and they include *C. Loreti* (*Iusitanicus*), one of the loveliest, with its graceful white petals with deep crimson spot at the base of each petal, one of the latest to flower with me, and it had a flower on as late as October 21, as also had *C. algarvensis*, which has flowered much better than usual this summer. *C. formosus*, which also has flowered fairly freely this month (October) is the form with the purple-brown blotch at the base of its bright yellow petals. I also have *C. formosus immaculatus*, with simple

still in flower. I have quite a number of *C. purpureus*, probably the best of the family, with its large crimson blossoms with a blotch of maroon at the base of each petal; this has been in bloom this wet season from June right up to October. *C. villosus*, with rose-coloured flowers, still has odd ones in bloom. Other *Cistus* which I have that have been out of bloom some time are *CC. corbariensis*, *corsicus*, *laurifolius*, *cyprus* and *cyprus maculatus*, the three last named sturdy, very free-flowering shrubs; *C. rosmarinifolius*, very slow growing and somewhat tender (but two specimens I have, have gone through the past six or seven winters); and *C. monspeliensis*, an upright growing species, covered with small dainty white roses, with a yellowish blotch at the base of each petal. The dwarf *C. alyssoides* I have failed to establish up to now and the true *C. ladaniferus* I do not seem to have, what was obtained for this proving to be *C. cyprus*, as is, I am afraid, very often the case.

Practically all the *Cistus* above mentioned have been raised from cuttings and all have gone through at least three winters and many eight or nine. The time when they suffer most is in the cutting frosty winds we often have in the spring. My *Cistus* are usually cut well back as soon as they are out of flower, this keeps down the straggly branches which the wind gets hold of in the winter thus causing the roots to be loosened so much that the wet and frost get in—probably the cause of many plants not surviving the winter period. It is also a good thing to examine the plants early in the autumn and, if at all loose, to fix them up to small stakes to prevent movement. The long continued wet weather that we have had in these parts since the middle of June has brought on a good deal of sappy growth which, if we have a severe winter, may be the undoing of some of them later.

The hardy shrubby *Potentillas* should be included among the smaller flowering shrubby plants worthy of more use in our gardens. The native *Potentilla fruticosa*, with its darkish green foliage and its innumerable simple golden yellow flowers—"glittering stars of gold," as Farrer describes them—is very beautiful when at its best and the flowers are produced over a considerable period. In addition to our native species, many good varieties have been introduced from the wilds of China in recent years, and all that have been tried (with the exception of a very dwarf form of *P. fruticosa nana*, planted at an unsuitable time), have succeeded in establishing themselves in my garden. These include *P. Vilmoriniana*, of more upright growth than *P. fruticosa*, with silvery grey leaves and large creamy white flowers and *P. Veitchii*, also of similar growth, with green foliage and white flowers. These two are usually pruned back after flowering to keep them dwarf. *P. sp. 188* Farrer has pendulous branches with smaller green leaves and small yellow flowers running along the branches; it is usually later in flowering than the others before mentioned. Another that I have was sent out as *P. fruticosa forma* (Forrest), is somewhat pendulous and has deeper yellow flowers—not, however, deep orange as it was described as having in the R.H.S. list. All the above have gone through three or more winters satisfactorily.

Spartium junceum, the Spanish or Rush Broom, is most useful for its late and free-flowering, its fragrant bright yellow racemes of flowers being freely produced, usually in early July, and if cut back a little it flowers again in the autumn up to the first severe frosts; it is very useful for cutting for inside decoration. Plants are best raised from seed, potted up until "pot-bound," and planted out with as little disturbance of root as possible, when, if not in too heavy soil, it should readily establish itself, that is if rabbits, which seem to

WHITE WITH CRIMSON BLOTCHES, *CISTUS LORETI*.

more stiff. *O. macrodonta* is more liable to suffer than the before-mentioned and very frequently gets partially cut back, but usually recovers quite well and flowers, although last winter my largest bush suffered badly in January and again later and had to have the damaged branches cut off, but it has come again quite strongly from the base; it is well worth having, both for its evergreen

yellow flowers, but this is only a recent addition. *C. salviifolius*, the sage-leaved *Cistus*, still has a few flowers on, as has also *C. florentinus*; this *Cistus* seems to have branches killed by frost at times, but usually has plenty left to re-establish itself. *C. crispus*, was later in flowering this year owing to being checked somewhat badly in the spring, but recovered completely and is

appreciate it only too well, do not find it. Several seedlings planted out were eaten down to the ground by them, one of the garden's worst pests.

Two specimens of *Buddleia Farreri* (one raised from a cutting), planted out last year came through last winter and have grown well with their large grey flannel-like leaves, but have shewn no sign of flowering; it apparently flowers in its native habitats in March, before coming into leaf. Is it

usual for it to flower in this country? The early spring up here is rather a trying time to have a *Buddleia* coming in bloom!

With reference to *Tropaeolum polyphyllum*, which was described in a recent issue, it is probably worth mentioning that the tuberous roots should be planted at least 18 ins. deep to ensure success in establishing it.

Middlesbrough. T. ASHTON LOFTHOUSE.

FLOWER HOUSE

The new Tenant—What next?—Earlham Montbretias—Phloxes in Sweet's British Flower Garden and in Jones's at Flower House

“WHERE there's a will, there's a way.” Where there's a Wales there's a Jones. Whenever any big herbaceous family comes into the limelight and is of sufficient merit and importance to be “handled” profitably, look out for *H. J. Jones*. These last two pleasantries are home-made, but all who know “Who's Who,” will agree that the fact in the first and the delicate insinuation in the second are credibly correct. Gold medals in the office at Hither Green, Lewisham, are no more “accounted of” than gold in Jerusalem when Solomon was king. It was the lure of his gold-medal Michaelmas Daisies that drew me to Hither Green as once before these grand autumn flowers had enticed me to the still more famous gardens at Aldenham House, where I was given a splendid treat and shown great kindness. I boarded the No. 10 tram at Victoria and was to be met by Mr. Jones at its country terminus, for he had explained to me that his original Ryeacroft Nurseries were full and overflowing and that we would have to go further afield to get to where the Michaelmas Daisies were. He met me all right and almost immediately we found ourselves in the grounds of what must have once been a fine country residence—Flower House, the home of the à Becketts. He had, he told me, been fortunate enough to secure four acres. Here he has Dahlias, Phloxes, Montbretias, Delphiniums and Michaelmas Daisies. Everything except the Montbretias were “in the pink.” These had suffered from the cold, damp time and some of the varieties looked rather sorry for themselves. I have never cared very much for His Majesty. Somehow it always seems to me to be over large and it was no surprise to find the flowers looking very sorry for themselves and bedraggled. Queen Alexandra, Nimbus and Queen Elizabeth are the three that I would select if I were choosing to please myself. The first of the three is a very pleasing shade of dark straw, the last is an orange-red, while Nimbus, as its name suggests, is distinguished from all others by the red halo round the centre of the flowers which recalls Gaillardias and certain forms of *Tulipa Kaufmanniana*. These Earlham Montbretias have revolutionised the race. I remember when we had to go to Lemoine for our up-to-date varieties.

Then came the Davidson hybrids, culminating in the fine orange-yellow Star of the East, which was considered so wonderful at the time it first appeared

THE LARGE MONTBRETIA HIS MAJESTY.

that it had the distinction of being the talk of a Shrewsbury Show. These have now been passed by the Earlham strain. The children have out-distanced their parents and instead of being content with Nelson, Lady Hamilton or even Prometheus, which I believe was raised in Holland, we must have His Majesty, Queen Alexandra, Citronella or Nimbus.

But Montbretias are not Michaelmas Daisies, and these are what I came to see. I saw them—quantities of them—but the fates had not been kind and only a very small percentage were in flower. I think the most attractive was one raised by Mr. Jones himself and named after the present

owner of Flower House, Major Pat à Beckett. It is a flower of the particular shade of mauve which always finds me and touches the approval spot in my brain. It is Euterpe against Ergaste in Tulips, and Gladys against Victory in Sweet Peas. *Cattleya*, a loose double soft pink shade and Ethel Ballard, a narrow petalled “mauve” pink, are the only others of this section down in my notes. Disappointed here, I had the compensation of learning something about the earlier flowering and dwarfier growing *Amellus* branch. It must in future be Rudolph Goethe and not King George, while there is undoubtedly no pink in the same boat with the rather difficultly named *Wienholtzi*. Mr. Jones's remark as we stood looking at it is one to read, mark, learn and inwardly digest. “Were I tied to one only of the *Amellus* lot, this would be my choice.” I saw the Delphiniums and made no note except that all seemed to be seedlings (and a very promising lot they were). I glanced at the acre or more of Dahlias and spotted *Salmonea* (a pretty salmon pink) and King of the Autumn (a lovely shade of pale apricot) but most of the time was spent among the Phloxes. This bright late-summer and autumn flower may be called a fairly popular one at the present time. History is repeating itself after an interval of nearly a hundred years if the numerous illustrations of different members of the family published in Sweet's “British Flower Garden,” from 1827 to 1831 are anything to go by. In those days the nursery of Mr. George Wheeler at Warminster was a great distributing centre, just as Mr. Jones's Ryeacroft Nurseries at Lewisham are now. The picture of *Phlox odorata* (Plate 224, first series) shows a very beautiful variety, with slender panicles of pretty bright rose-coloured flowers a foot or over in length, and which from the description were very sweet and retained their scent in dried specimens. It is of particular interest because the long panicle is a breakaway from the ordinary pyramid shaped ones with which we are now so familiar. What struck me on my visit to Flower House garden was the large number of dwarfs. It had never occurred to me that there were so many. I mention it because it is a useful bit of knowledge. In this age of manufactured bigness, some niches still remain which only small plants can properly fill. I am leading up to the suggestion of a late-flowering Phlox border where dwarfs would be wanted for the “front seats.” Phlox means flame. A border of flame! Yes, but only conventional flame. Yellow is conspicuous by its absence in the family—so I would rather say, a border of brilliant magnificence. On turning to my notes I find that quite unconsciously a goodly number of my selections would be admirable for such a purpose. It was a lovely day and I know I went very largely for the bright colours, much I fancy to Mr. Jones's amusement, who has, I think, rather a penchant for the salmon—not quite so much, however, as I have for the real thing—I went for red and cerise and rose more than anything else. Here are my dwarfs. Commander-in-Chief, deep rose with a dark eye; Mont Pelée, orange-red; Jules Dandau, dit., cerise; Florrie Freeman, a pale rosy-scarlet; Selma, soft pink, with a darker eye; Jones's Pink, pink; and Mauve Queen, a pretty shade of heliotrope with a white eye. The taller ones were (1) Charles Davies, a rich rosy crimson, in my judgment the brightest and gayest variety in the whole of Mr. Jones's Phlox patch. (2) September Glow. I think my host considered this his gayest and brightest. There was more of it and it was in better condition and the freshly opened blooms had a touch of salmon, which evaporated with age, leaving behind a glorious rose red. (3) Egir, medium height, brilliant scarlet-red. (4) Rosamundi, a pretty pink with a soft rose eye. In Tulip language the petals quarter, but the Bohemian

sort of look rather suits it. (5) Mrs. H. J. Jones—before I knew the name I said, "that's a saucy looking piece." The mauvy-pink body colour of the petals, some tipped with rose, some half inclined to show quartering and the extra large bright carmine eye, compose a charming truss, at once vivacious and fascinating. (6) R. A. Goldie—it has got out of place in my notes—the catalogue description is *very dwarf*. It is an undoubted salmon red with

a large rose eye—large too in pip and truss. If you must have a dwarf salmon, try this. Mr. Jones gives it a capital character. "It is always up to the knocker." This is my "lastly." But the pic is a very large one. It contains 181 plums, so allowing Jack Horner his one, and J. J. his baker's dozen, there will still be enough left for many more thumbs. Mark well my words, "H. J. J. is a grand maker of Phlox Pic." JOSEPH JACOB.

because this necessarily involves foundation laying, a task which will have to be learned by patient practice and close observation. Instead he should have three year olds or, if the slightly increased cost does not worry him, four year olds, whose foundations have been formed already in the nursery by men of skill in the craft. In addition to the shapely head there must be an admirable rooting system, largely fibrous in its nature and such as will be secured in trees purchased from the reputable fruit nurserymen who do not fail to advertise their wares in the fertile pages of THE GARDEN. There must be no seeking to the uttermost ends of the earth to find something a little cheaper—no, not cheaper—lower in price. The fruit nurseryman transplants his stock and thus ensures a rooting system which is directly favourable to transplantation; the vendor of low-priced stuff cannot afford to do that and the comparisons will work out at failures conspicuous by their absence from the reliable source and successes conspicuous by their absence from the unreliable one. Our head gardener must avoid so-called cheap trees as strenuously as he would avoid the plague.

If the roots become dry before it is convenient to plant the trees, soak the roots in water for twenty-four hours or so to plump them up. Go over them with proper care and cut back to sound portions any which have been broken or bruised in transit. A safe guide for depth of planting is to take the nurseryman's line, which is always correct for his own soil; or to accept the rule that the uppermost roots should never be covered to a depth exceeding gins. Friable mould must be worked thoroughly between the numerous roots, and there can be no doubt that fresh loam is the best soil for the purpose, but it is not always at command.

Then the head gardener must keep in his mind that firmness is essential, that, indeed, firmness to the point of solidity is of outstanding importance. It is impossible for one who is endeavouring to give helpful hints to brethren whose learning is presumably less profound to stress this point to excess, since it is incontrovertible that as much disappointment with fruit arises from looseness of the soil about the roots at planting time as from all other causes in combination. Spread the roots fully out, make absolutely sure that all are completely surrounded with friable soil and drive the mass down with a rammer. In advocacy of desirable firmness one hesitates just short of carrying it as far as the hardness of the macadamised road. It is thrifty growths to which firmness at the roots is directly conducive that we want in our trees and not long, luxuriant, sappy shoots which are favoured by looseness, especially when, as is frequent in gardens, there is a greater depth of root run than is really necessary, or than is even desirable.

The first pruning or cutting back should be done immediately on planting in nearly all instances and the head gardener of the medium-sized garden who does not feel himself qualified to decide to what degree the reduction ought to be carried should pick somebody else's brains. Instantly comes the question from several head gardeners, "Whose brains?" and with equal promptitude the answer is Mr. Owen Thomas's in "How to Prune Roses and Fruit Trees" (*Country Life* Offices, 11rd., post free). If it can be managed all planting should be done in November and that which remains undone at the end of the month named, at any time thence to the end of March, when the condition of weather and soil permits.

THE KINDS TO GROW AND THEIR POSITIONS.

In a brief review of the kinds which ought to be grown it may be well to commence low

FRUIT FOR THE MEDIUM-SIZED GARDEN

IT is necessary as a safeguard against possible misunderstandings that readers and writer shall become sufficiently *en rapport* as to agree, at least broadly, on what is meant by the term "medium-sized garden." The writer's conception is one of which the owner is the head gardener and he does practically the whole of the work among the flowers himself, superintends the working of the vegetable department more or less perfunctorily, but generally leaves it, with sole charge of the fruit trees and bushes to the "expert" care of the jobbing man, who attends on one, two or three days a week, according to the actual size of the place and the standard of its upkeep. The head gardener here sets out upon his task with the satisfactory feeling that he knows enough about flowers to take complete control, sufficient about vegetables to enable him to guide the sometimes erring hand and nothing whatever about fruits, and therefore he leaves them severely alone.

In my opinion, and I state it without the slightest hesitation and in the almost certain knowledge that it will be vigorously disputed by some of the keen men, and women too, who read THE GARDEN, the head gardener is proceeding on the worst possible lines. Instead he should grow his own fruits, grow or supervise to the uttermost limit his own vegetables and leave the flowers to the man. The successful production of excellent fruits and vegetables demands more intelligence than the successful production of flowers and it is in that direction, therefore, that the head gardener should take, and keep, his way. It may be well, as a set off to the critics, to mention that in making this statement, all consideration of the head gardener who grows Roses, or Dahlias, or Sweet Peas or Carnations as a speciality is ignored.

ANCIENT, ERRONEOUS IDEAS.

From time immemorial or from those long gone past days which the journalist would assure us are "lost in the mists of antiquity," the idea has prevailed that fruits can be successfully grown only by those who have made them a life-long study and that there are mysterious little things which must be done to them from time to time that are known to the profoundly learned alone. Never was there a more erroneous or ridiculous fallacy. I assert, and that without fear of substantial refutation, that there is no point in connexion with the culture of any of the fruits grown in British gardens with which the man of intelligence cannot make himself perfectly familiar in the course of two or three years, provided, and it is an important proviso, that he is determined to do so. The weather will bring him a purler sooner or later of a certainty, but it will inevitably bring the profoundly learned down with just as big a crash. If the theme of the moment were growing fruits of all kinds under glass, a different tale would have to be told and even then the lessons

could be learned, though they would demand a longer period of study.

There is no mysterious art in planting, training, pruning, thinning, gathering, feeding, cleaning or storing. Given a modicum of intelligence and commonsense in its application, fruit growing in a medium-sized garden will be a fascinating and a successful pleasure and it will be all the more fascinating, successful and pleasurable if the head gardener controls it himself. The unfortunate individual who has neither intelligence nor commonsense should not set foot inside a garden gate since he will never be able to grow either flowers, vegetables or fruits.

GETTING READY—SOME SPADE WORK.

As it is with everything else, so it is with fruit culture—there must be preparatory operations, and seeing that we do not plant fruit trees or bushes to occupy their sites for one season, but for a decade or a generation or considerably longer, it is obvious that all the preliminary details must be thoroughly attended to in a workmanlike manner. In these days of plentiful drains it is improbable that the medium-sized garden will ever become waterlogged; on the contrary, it is much more probable that excessive drainage will prove the disability. If there is a danger in the former direction, drains must be put in and that is a task which the head gardener will wisely relegate to one who has the necessary knowledge; while if the soil is apt to run too dry, it must be strengthened by the addition of clay or better still, burned clay, or failing that, by very real consolidation.

Assuming normal conditions the soil must be thoroughly worked to a depth of 18ins. by perfectly digging the top spit and efficiently loosening the under stratum. Here the head gardener may proceed by deputy, provided that he sees the operation is done and that there are no miserable apologies, such as are far too common in the work of the "expert" jobbing gardener who, as a matter of fact, is frequently a drifter who comes in because "anyone can do gardening." If it can be managed, digging must be done not less than three weeks in advance of planting and, failing that, the soil must be artificially firmed in the second spit first and the top spit in its turn. Lime can invariably be added on the surface, either before or after planting, to advantage, since should there be enough present, which is seldom the case, it will do no permanent harm, but it is in the rarest cases only that manure should be incorporated. Indeed, it is wiser always to vote against it as feeding can be done later, as judgment decides, without trouble.

TREES, ROOTS, PLANTING.

The head gardener of the medium-sized garden should not accept the advice, indisputably excellent as it is to the man who is already "profoundly learned," to plant maidens or one year olds,

CORRESPONDENCE

and work upwards, because there may be medium-sized gardens in which the head gardener cannot find accommodation for some of those trees which demand a substantial amount of space.

Strawberries come first then. All things considered they are best worked into the ordinary rotations of the vegetable section, as it is easy to maintain the three yearly cycle in which quarters which have fruited three times are grubbed annually and an equal area is planted with perfectly rooted runners. These plants constitute the one variation from the rule of November planting. The best season for them is August or early September, as there is then a reasonable certainty that the crop will be heavy and excellent in quality in the summer immediately following. Failing space in the vegetable or other department they can be grown as edgings to the paths; set them not less than 18ins. and better 24ins. back and treat them as "annuals," planting afresh each year.

There must be at least one or two rows of Raspberries, allowing not less than 4ft. asunder with 2ft. between the individual plants. The single stem of every plant ought to be cut down to within about 6ins. of the ground as soon as planting is finished and in no circumstances should the occasional late blossoms which come be permitted to remain the first summer subsequently. It is well to note that this fruit does not thrive to perfection on a cold, tenacious clay on the one hand, or a hot, thin sand on the other hand; the ideal is a medium loam.

Black Currants are partial to a cool, holding soil and they must be represented notwithstanding big bud and the intimately associated "reversion." A distance of 5ft. in all directions should be given and in pruning the oldest wood must be removed first and then such of the young as is necessary to admit light and air unobstructedly to the young shoots retained.

Red Currants and Gooseberries rank among the "must be's," with one or two White Currants, if the fancy so dictates. They are usually grown as bushes at 5ft. to 6ft. apart all ways, but much superior quality will be secured from single or multiple stemmed plants trained to strained wire trellises not less than 6ft. in height or to north walls where nothing else flourishes profitably and where the fruits hang very late indeed, provided that they are efficiently netted against birds. As single cordons 1ft. is ample space and the yields on healthy plants are simply enormous. The most popularly recommended fruit for a north wall is the Morello Cherry, but it is not nearly as generally useful as either Red Currants or Gooseberries and these should, therefore, be given the preference. Besides, brandy is expensive these days—but enough on that point.

Apples, Pears and Plums in bush form are almost indispensable in the medium-sized garden, but if it should be decided that one of them must be omitted, let it be the Pears, as they are never so reliable in the open garden as the others. The soil will be that natural to the garden and it must contain lime, with more for the Plums than the others. A distance of 8ft. asunder may be allowed and when the trees meet later each alternate one must be grubbed for destruction, or transference to another position if required. There may be, too, one or two Sweet Cherries, but they are never very satisfactory in the medium-sized garden because the birds demand so heavy a toll in the absence of costly and always somewhat difficult netting. A final word may be said. Do not leave an inch of wall or fence space unoccupied. There is a fruit which will clothe it at once handsomely and profitably, but exhaustive consideration of this phase of the subject must stand over.

W. H. LODGE.

THE CHALLENGE CUPS OF THE ROYAL HORTICULTURAL SOCIETY.

THE Council has now decided to abandon the rule by which the same competitor could not win the same challenge cup in successive years. In future he may win it year after year until he is beaten in the competition.—W. R. DYKES, *Secretary, Royal Horticultural Society.*

THE BEST ROSES.

AT the present time, when so many notes and articles on Roses are appearing in your valuable paper, I should like to draw attention to a very beautiful variety that seems to be greatly

preference would be my selection: (1) Hugh Dickson, (2) Harry Kirk, (3) Lady Pirrie, (4) Red Letter Day, (5) Mme. Abel Chateau and (6) Christine. I am sure the above selection will be severely criticised by lovers of the newer, more brilliantly coloured Roses, but in this garden, situated in Ulster, the above-mentioned varieties have proved themselves in every way worthy of attention, especially Nos. 1, 2, 3 and 4, which I would plant more freely than the other two. Hugh Dickson is magnificent as a standard, and is at its best as such. If another six sorts were required I would add Augustus Hartmann, Lady Ashdown, General McArthur, Lyon, Miss Willmott and Lieutenant Chauré. If five red Roses were considered too many in a collection of a dozen, I would substitute Mrs. A. R. Waddell for Lieutenant Chauré and Mrs. Henry Balfour for General McArthur. Isobel and Simplicity are two fine single varieties. —CECIL M. BAILEY.

THE HARDY JAPANESE ORANGE

DESPITE the somewhat unfavourable season, the Japanese Orange, *Ægle sepiaria*, seems to have fruited freely this season in many gardens, though I do not know of any having ripened. The curious little downy fruits are distinctly attractive and the blossoms beautiful, and it is rather strange that so interesting a shrub should be so comparatively seldom seen. Its entire hardiness is unquestionable, but it does not appear to flower so freely in Northern gardens as it does further South. The fruits are not poisonous, but are so acrid as to be quite inedible. There was a note by Lady Moore in *THE GARDEN*—I think last year—on the Citrange, which is a cross between the *Ægle* and the Sweet Orange. It would be interesting to hear to what extent this has proved hardy in England.—H. H.

[The article referred

to was published on March 4 of this year, page 105. If any readers have had experience with the Citrange in Great Britain, perhaps they will give us the benefit of their experience.—ED.]

THE TWELVE BEST SHRUBS.

THE discussion on this subject has interested me from the first on page 507 to page 550. I quite anticipated differences of opinion, being always in that mood myself. I have often been asked to give the best twelve or six, although I confided to myself that there was no such thing, just as expressed by Mr. Slinger on page 545. In the first place I decided for hardiness according to the part of the country from whence the enquiry came, and ease of cultivation, but often had to

A FRUITING SPRAY OF THE HARDY JAPANESE ORANGE, *ÆGLE SEPIARIA*.

overlooked during the present craze for new and striking colours, namely Harry Kirk. In the writer's opinion Harry Kirk is one of the most reliable, as well as one of the most beautiful, yellow Roses on the market, even though it is not of such a deep or striking shade of yellow as Christine, Golden Emblem, Mrs. Wemyss Quin, etc. The buds are deep sulphur yellow streaked with crimson, while the expanded flowers turn to a pale sulphur. It is splendid either as a dwarf for bedding or as a standard, and for table and house decoration is unsurpassed by any of its more gaily coloured rivals. It is also sweetly scented, which nowadays is, in my opinion, worth consideration. If I had room for six varieties only, the following in order of

hesitate on the score of the taste of the individual. This latter is borne out in everyday experience, and by the examination of various gardens, irrespective of size, I give the following as an excellent dozen without priority of merit: *Berberis Darwinii*, *B. stenophylla*, Lilac Mme. Lemoine, *Ceanothus Gloire de Versailles*, *Pieris japonica*, *Ribes sanguineum*, *Forsythia suspensa*, *Cytisus albus*, *Cratægus Pycnantha Lalandei*, *Eucryphia pinnatifolia*, *Magnolia Lennei* and *Prunus triloba flore pleno*. All of the above admit of massing, and the last named can be kept down to 3ft. by annual pruning as soon as the flowers fade. All, I think, could be grown in Cornwall, Nairn or Co. Down; but there are many inland counties where the *Ceanothus*, *Pieris*, *Eucryphia* and *Magnolia* might fail to give satisfaction. The lists already given ought to be valuable to planters—J. F.

I WAS much interested in your issue of October 28 to see the correspondence with regard to the Twelve Best Flowering Shrubs. I should much like to add the twelve which I consider most worthy of cultivation, and I beg to submit the following:—*Embothrium coccineum*, *Feijoa Sellowiana*, *Carpentaria californica*, *Pieris japonica*, *Andromeda cassinefolia* (*Zenobia speciosa*), *Tricuspidaria lanceolata*, *Callistemon speciosus*, *Drimys Winteri*, *Drimys aromatica*, *Plagianthus Lyallii*, *Eucryphia pinnatifolia* and *Eucryphia cordata*.

I fear that most of the above would only flourish in a mild climate. I grow them most successfully on the West Coast of Argyllshire, but I have been quite successful in growing, against a wall, in the West Riding of Yorkshire. *Drimys Winteri* and *Carpentaria californica*. There are many shrubs that I should like to suggest, but as your correspondent mentions twelve, I do not like to exceed the number.—(Mrs.) GWENDOLEN GASCOIGNE.

THE CAUCASIAN SCABIOUS.

READERS OF THE GARDEN who have a liking for lavender shades in flowers could not do better than go in for a stock of this lovely Composite. As a distinct, prolific and lasting plant for the herbaceous border it has few equals, and as a cut flower with its strong, long, accommodating stem, it is superbly decorative, lasting a long time in water, especially when the latter is frequently changed. The seeds are not very dear. Two shillings invested in a packet from a reliable firm gave us our sturdy stock. These were sown early in January in well drained pans in a fine compost of equal parts of loam, old mushroom-bed manure and sea sand. Gently watered, they were then placed upon a shelf near the glass in a temperature of about 50°, and germinated in about two months. When they were large enough to handle, they were potted off singly into 2½ in. pots in a similar compost to that in which they were sown. After planting them out in a well manured border in late May, they made good progress, and commenced to throw up their sturdy flower-stems in August. Though classified as a hardy perennial in most catalogues, this plant will not stand the rigours of a severe winter outside. This we found out to our sorrow in our first year's experience with it. In our second year's trial we took up the plants full of buds and flowers, and potted them into 6 in. pots in October and placed them in a cool greenhouse. What a wealth of bloom we had from them all that winter! In fact, this plant, with its clean, shining, rich green foliage, if given favourable treatment, would seem to flower for ever.—ROBT. MCHARDY, *West Derby*.

ABOUT SINGLE ROSES.

I QUITE agree with Mr. Jacob (pages 553-4) that we ought to collect and grow the single wild Roses that are offered us by enterprising

nurserymen in order to encourage them in this good work. When Roses have attained such a vogue as at present, I am surprised that no one in this country seems to have conceived the idea of making large or representative collections of Roses, single and double, in private gardens. More single wild Roses, however, are offered by the nurserymen than is apparently generally known. The late Mr. George Paul, who catered so long for our delight, and who gave us the best coloured Hawthorn—Paul's Scarlet Thorn—seventy-one years ago, also offered forty-three species and seventeen or more varieties of single wild Roses exclusive of the varieties of *Rosa rugosa* and its hybrids. Among them he offered *Rosa sancta*, which he considered probably the oldest Rose in the world. Another of recent introduction was *R. lucens*, the stems, leaves and even the thorns of which appear lacquered. He had awards of merit for two hybrids of this which he had produced. In another British Rose catalogue I notice thirty-two species and six or more varieties of single wild Roses offered. Twenty species and seventeen varieties, ten species and seven varieties, ten species and three varieties, and seven species and three varieties are offered in four other British catalogues which I have consulted. Such enterprise deserves encouragement.—HORTULANUS.

[Mr. T. Smith of Daisy Hill Nurseries, Newry, Ireland, offers no fewer than eighty-one species and sub-species in his list.—Ed.]

AN INTERESTING DELPHINIUM.

THE name of Delphinium inevitably brings to us pictures of the towering spikes of the hybrid Delphiniums, so indispensable in the herbaceous border, presenting as they do some of the greatest triumphs of the florist's and seedling raiser's art. In *Delphinium Brunonianum* we have, however, a Larkspur of quite different character and one which appeals more to the lover of distinct things than to him who is devoted to grand spikes and showy flowers. It is a low-growing species, rarely more than 2ft. high, and frequently less, and having quiet and quaint-looking flowers of purple which seem at times as if they had been dimmed on the surface yet not had their beauty destroyed. The plant is musk-scented, too, which gives it a distinct feature. It is not difficult to grow in ordinary loam, and can be suited well in the border. It is hardy and can be raised from seed or increased by division. There are two plants in nurseries under this name. They are alike in many points but distinct in others, and it is difficult to say which is the true species. Probably both are geographical varieties of the same plant.—S. ARNOTT.

[According to the late Reginald Farrer ("The English Rock Garden"), *D. Brunonianum* is a "curiosity from the high Alps, not more than a foot in height at most with large and rounded hairy flowers of pale blue in a loose and long peduncled corymb. The *D. Brunonianum* of gardens is usually of a deep and very sombre purplish black." The identity of the

plant known in gardens as *D. Brunonianum* seems wrapped in mystery. Perhaps some of our botanical correspondents can help to unravel the matter.—Ed.]

SEASIDE FLOWERS.

I AM enclosing a picture of a rock garden built facing the sea at Walton-on-Naze, which I think you may find interesting as shewing how well many plants succeed at the seaside. The following plants were in bloom at the time of my visit: *Verbascum Caledonia*, *Anchusa Opal*,

A SEASIDE ROCKERY.

Lupinus polyphyllus Moerhousii, *Verbascum densiflorum*, *Fuchsia Riccartoni*, *Spartium junceum*, *Cytisus præcox*, *Cytisus Daisy Hill*, *Cytisus Moonlight*, *King of Delphiniums*, *Foxgloves*, *Salvia virgata*, *Yuccas*, *Aster Amellus* in variety and *Erigeron Quakeress*: all these in the background. In the front of these there are *Geum Mrs. Bradshaw*, *Statice latifolia*, *Anemone Mont Rose*, *Verdona*, *Anthemis Cupaniana*, *Anthemis Kelsey's var.*, *Gypsophila paniculata*, *Sun Roses*, *Cistus* in variety, *Hencheras* in variety, *Enothera speciosa*, *E. Arendsii* and *Kniphofia caulescens*.

Rock plants in the foreground include *Saxifrages*, *Sedums*, *Violas*, *Veronicas*, *Aubrietias*, *Phlox subulata*, *Dianthus*, *Minulus*, *Primulas*, *Nepeta*, *Papaver alpina*, *Linums*, *Oxalis*, *Iris pumila*, *Lithospermum prostratum*, *Armerias*, *Artemisias*, *Arenarias*, *Campanulas*, *Alyssum*, *Cheiranthus Allionii*, *Audrosace Chunbyi*. Most alpines do well near the sea, and it is strange they are not more largely grown.—H. W.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Asparagus.—Where early supplies of this vegetable are required some arrangements should be made now to get the roots into their forcing quarters. One of the best places for bringing the grass along is a moderately heated range of pits facing south. Into these throw some stable litter and leaves well mixed together and sufficient to form a firm bed of about 2ft. Place on the top a layer of about 3ins. of sifted leaf-soil, then the roots to be forced, placing them quite closely together, and finish by covering with another 3ins. of fine leaf-soil. Give a good watering through a roset can and afterwards keep roots and atmosphere in an even state of moisture.

Broad Beans.—Unless the district is very cold and the soil a heavy one, there is certainly a gain in making an autumn sowing of Beans. While this vegetable delights in an open position generally, it is better to try to make this sowing in one a little protected. Space the seed in double drills about 3ins. apart, allowing a distance of 2ft. between each set of drills.

Peas.—Autumn sowing of this Legume is not practised so much as of the former, and, probably, where there is plenty of convenience for bringing along plants in the New Year previously to planting out, there is but little to be said in its favour. On cold soils the plan is certainly not worth carrying out. Where a sowing is made, choose a warm, well drained border and select a round-seeded variety, such as Pilot, which is one of the best I know for autumn sowing.

The Flower Garden.

Overcrowded Shrubberies are by no means an uncommon sight, owing in great measure to unsettled staff conditions. It may be that judicious pruning consistently followed for a few seasons will remedy some of the evil, but where several years of unavoidable neglect has to be dealt with it may be a wiser policy to remove some of the trees and bushes rather than overdo the pruning. Oft-times there is many a spot in the woodland near the dwelling which is admirably adapted for the surplus stock from a too thickly populated shrubbery. Now is the time to do the work.

The Reserve Garden may be called a necessary and most useful portion of the garden, particularly where large general supplies of bedding and other plants, as well as plentiful supplies of cut flowers, are required. The best and most convenient arrangement of such an enclosure would consist of simple narrow beds so that it is easy to pass between them to give necessary attention, etc. The portion devoted to plants grown to supply cut flowers should always be well cultivated, but it is not a good or a necessary procedure to have a great depth of rich soil in the beds used as nurseries for growing different plants on for removal later.

The Hardy Fruit Garden.

The Orchard.—There is no prettier spring picture than an orchard of fruit trees in flower, especially when drifts of Daffodils are added to it. Where a new orchard is in contemplation the ground should be well cultivated and thoroughly cleaned. Unless, of course, the whole of the ground is to be cropped, *i.e.*, between the rows of trees and between the trees as well, it is a waste of time and quite unnecessary to turn over the whole, but only where each tree is to be planted. Give the warmest positions to dessert fruits, plant firmly and stake securely. Any necessary pruning in established orchards can be dealt with as opportunity may offer during the next three months. There may be but little required other than cutting out to prevent the centres of the trees becoming too thick and the shortening of a few branches to keep a better balance. Also remove entirely branches which cross each other, and among old trees there will almost certainly be a few dead and decaying portions to cut away.

Fruit Under Glass.

Early Vines.—Should it be the aim to make a start by closing the house or pit in early December, permanent rods or pot plants should now be got ready by pruning and cleansing if not already seen to. Should mealy bug have been allowed a footing, every possible care should be taken to see that the cleaning, both of the plants and the structure, is very thoroughly done. Having put these two in order, any necessary work to

the border can be done. First of all remove every bit of loose manure, etc., then lightly prick up a little of the border, removing this also if at all sour, then apply about 3ins. of broken fibrous loam to which has been added a little old rubble, some wood-ash and a few fine bones. This top-dressing must be firmly done.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cucumbers.—In pits where late batches of Cucumbers are coming into bearing they may be assisted with some quick-acting fertiliser. Should ordinary liquid manure from the byre be favoured, see that it is used in sufficiently warm a condition to cause no check to the tender surface roots. Keep all unnecessary growths in check, damping down only on bright days, at the same time keeping up a brisk and even temperature by the judicious use of fire-heat.

Tomatoes in Pits.—For early fruiting these plants must also receive strict attention at this time by keeping the temperature of the structure buoyant. A close atmosphere with too much fire-heat encourages soft growth which can ill resist the attacks of insect pests. Aim at having firm, stocky plants, keeping them as near to the glass as possible. While the plants should receive a thorough watering when necessary, added care must be taken to see that none gets the least water-logged, as nothing tends towards the failure of the early spring crop more than careless watering.

Forcing Asparagus.—Preparations for the forcing of this delectable vegetable should be made from now onwards. A heated pit is best for this purpose, and saves both time and labour. However, where accommodation cannot be spared indoors, excellent results may be had with the aid of a fermenting bed of stable litter and leaves. The latter being available in quantity now, a bed may be made up of one-third manure and two-thirds leaves. If the materials are turned a few times previously to forming the bed, sufficient heat will soon be developed for forcing Asparagus. The bed should be made large enough to hold one or two frames as desired. When ready for planting the roots should be lifted or strong crowns procured from a reliable seedsman, placing them closely together on a layer of old potting soil and packing firmly round the crowns with similar material. The temperature of the frame should be kept about 55°. When mild, sunny weather prevails admit air to keep the growths from becoming drawn and weakly. Cover the frames with mats should sharp frosts occur.

Parsnips.—It is not absolutely necessary to lift and store Parsnips for the winter, and many growers leave them in the ground until early spring. It is advisable in cold districts where frost and snow are frequent to lift and store in a cool shed, covering the roots over with sand or fine soil. Treated thus they will be found to keep perfectly succulent and free from that toughness so common with badly stored Parsnips.

The Hardy Fruit Garden.

Fruit Trees on Walls.—A start should now be made on the pruning and training of fruit trees on walls, so that as much work as possible may be completed before the winter is too far advanced. Should the ground be wet, several rough boards may be laid along part of the border. The work may then be done more comfortably, while trampling of the surface of the border is prevented. Where the growths of Morello Cherries have become congested the branches should be loosened from the wall and all worthless shoots removed. The main branches should then be evenly distributed over the allotted space, while the strong young fruiting shoots should be tied in about 6ins. apart. The pruning of Sweet Cherries is entirely different from that practised in the case of Morellos, for the Sweet Cherries fruit best on spurs. Where summer pruning is done spur formation is encouraged and the trees require little attention now.

The Flower Garden.

The Herbaceous Border.—The occupants of the herbaceous border having now passed their flowering period, may be cut over and the borders made clean and tidy for the winter. A dressing of well rotted manure or the material from a spent hot-bed should be applied now, pointing it lightly

in. In borders where quantities of bulbous plants are grown the work of forking over is best left until the spring or such times as the majority show above the surface.

Violets in Frames.—To prevent damping, the plants need to be examined at regular intervals, removing all decaying foliage. Admit air on all favourable occasions and protect from frost by suitable coverings.

JAMES MCGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Tibouchina semidecandra, also known as *Pleroma* and *Lasiandra*, is a fine plant for autumn and winter flowering, and for some weeks now has been producing its large purple flowers with great freedom. It may be used for clothing a pillar or rafter in the conservatory, but is seen at its best when it can be trained over a wall or the gable end of a conservatory. It is best planted out in a restricted root-run, as it is a rampant-growing plant and requires considerable space to display itself to the best advantage. During the spring the plant should be pruned hard back, and as it breaks freely, some of the weaker growths should be thinned out. During the spring months it is easily propagated by means of the smaller twiggy shoots and as cuttings. If the plants are kept regularly pinched until August they form nice bushy plants in 6in. pots for the stages, and to ensure freedom of flowering they should be well exposed to sun and air to ripen the wood.

Peristrophe speciosa is another useful plant for autumn flowering, as it produces its flowers freely over a long period. The flowers are reddish purple, almost magenta in colour; not a popular colour it is true, and requires careful placing, although it groups well with pale yellow. A native of the Himalayas, this is easily propagated during the spring by means of cuttings, and succeeds under perfectly cool conditions throughout its growing season.

Lindenbergia grandiflora is another Himalayan plant with pale yellow flowers that is useful for autumn and winter flowering. This plant is also easily propagated by means of cuttings during the spring, and requires cool treatment, but it is by no means such an easy plant as the *Peristrophe* to grow successfully.

Philesia buxifolia is a very beautiful Chilean plant which is hardy in the West. Its red flowers are like miniature *Lapageria* blossoms. *Philageria Veitchii* is a hybrid between *Lapageria* and *Philesia*, and is probably very rare in cultivation to-day. The *Philesia* is a rare-loving plant, and succeeds in a similar compost to the greenhouse *Ericas*. It enjoys a cool, moist atmosphere. This is by no means an easy plant to grow successfully, but is worth some extra trouble, as a well grown specimen in full flower is very beautiful indeed. Its propagation by means of cuttings is slow and uncertain, and it is best increased by layering, which is easily done by using the suckers it sends up from the base of the plant.

Lapagerias.—Where a suitable situation can be found, *Lapagerias* are beautiful climbing plants for the conservatory. They do best on the coolest part of the house and do not object to partial shade for at least part of the day. Good specimens may be grown in large, well drained tubs, but they are seen at their best when they can be planted out in a well drained bed or border. If planted in such positions it is well to confine them to a portion of the border by means of slate slabs. This is necessary as they travel so far at the root and send up suckers where they are apt to get damaged. Slugs are very fond of the young shoots, and often do much damage unless they are carefully guarded against. Some cotton wool wrapped round the base of the young shoots until they become hard is a good preventive. The sites for the plants should be well drained, and the compost should consist of good fibrous peat and loam, which is best used in a rough, lumpy condition, with plenty of coarse clean sand to keep the whole open and sweet. It is also an advantage to add some charcoal to the compost. *Lapagerias* are subject to attacks of a small white scale, and now is a good time to take down the plants, thin them out where they require it, and clean them thoroughly before retying them. This requires to be done with great care, as the shoots are very brittle and easily damaged. *Lapagerias* can be propagated by means of cuttings, but it is a slow and uncertain process, and they are usually increased by layering; they then take twelve months to root, which accounts for the fact that plants are always fairly expensive.

Royal Botanic Gardens, Kew.

J. COURTS.

THE FORTHCOMING BRITISH EMPIRE EXHIBITION

Its Horticultural Possibilities and the Facilities Afforded.

THE British Empire Exhibition, which will open at Wembley Park, London, in the summer of 1924, will devote considerable space to British horticulture. The gardens that are now being laid out will not only be a worthy setting for the largest and most influential exhibition that has ever been held in the Empire, but will furnish a complete record of the development and progress of our horticultural industries.

Their extent and importance are, indeed, far greater than is generally realised. Exhibitions held periodically under the auspices of the Royal Horticultural and other societies afford some idea of what is grown, but their limitations with respect to space and time prevent that full and continuous display which would adequately present British horticulture in all its aspects. The facilities that can be afforded at Wembley Park will, if taken full advantage of by the horticultural trade, be a great improvement on all previous efforts for the advancement of the various industries concerned. The areas that are being reserved will be prepared with suitable soil for the permanent occupation of groups of hardy trees, shrubs, herbaceous perennials and all kinds of summer-flowering plants. Suitable conditions will also be available for a great display of bog and water-loving plants in and about the margins of the several lakes in the park.

It is intended to retain the existing sylvan beauties of the Park, adding to them all the best that horticultural art can provide. To do this the aid of all our great nurserymen and florists is being sought, and they will be assisted by the Exhibition staff in the planting and care of their exhibits. It is expected that the grounds will be ready for all permanent planting by next spring with a view to getting the plants established and in growing order by April, 1924, when the Exhibition will be opened. A Committee of experts experienced in the organisation of horticultural exhibitions will supervise the arrangements.

When the lay-out of the grounds is completed and the allotment of space decided upon, it is intended to prepare plans of the various sites that will be available for a horticultural display. No charge will be made for these sites, the only condition being that they should be furnished with plants in keeping with their surroundings and maintained in good order throughout the period of the Exhibition.

Special provisions are also being made for exhibitions of tender plants, *i.e.*, Orchids, Palms, Ferns, etc., also for fruits and vegetables, and the committees of the several horticultural societies are being invited to hold their exhibitions at Wembley in 1924. A large hall with a floor area of about 12,000ft. and ample top light will afford space and suitable conditions for this.

Provision will be made in one of the main industrial buildings for the display of models of greenhouses and other structures, statuary, machines, hot-water apparatus, implements, garden furniture, plant foods, insecticides and fungicides, and horticultural sundries generally. These will be on show if desired during the whole period of the Exhibition. A charge will be made for space for such exhibits, particulars of which will be furnished on application. Sites can also be hired in the open air for the display of full-sized greenhouses, summer-houses, garden seats

and other articles which do not require to be under cover.

The accessibility of Wembley Park from London and the provinces is exceptional. No exhibition site has ever enjoyed such traffic facilities. There are two main line stations close to the grounds, and the great trunk lines of Britain will be able to run trains direct to the Exhibition. There is, further, direct and quick railway, tram and motor 'bus communication between Wembley and all parts of London. A few of the distances by train are: Baker Street, 10mins.; Charing Cross, 18mins.; Euston, 15mins.; Paddington, 14mins.; Richmond, 20mins.; and Willesden, 5mins. A special siding for goods has been constructed within the Exhibition so that it will be possible for packages of plants, etc., to be conveyed direct from nurseries, etc., to the exhibitors' stands.

The Exhibition will be open daily from April till the end of October, 1924.

BOOKS

A Flora of the Riviera.—Mr. Stuart Thompson's book on "Flowering Plants of the Riviera,"* a copy of which was recently received for review, is not exactly new. It was, indeed, published as long ago as 1914, but the thoughts of all of us were, at that time, directed to quite another part of France! The work is excellently got up and arranged and should be invaluable to anyone contemplating botanising along the *Côte du Sud*. Even to the more casual amateur gardener-botanist it should be very helpful, for it is far more interesting if one can readily trace the name and lineage of some new plant which one admires. Brief but adequate descriptions are given of about 1,800 plants and twenty-four plates illustrate in colour no less than 112 of the species, while there are sixteen photographs of the vegetation. An admirable chapter on collecting and preserving plants is not the least valuable part of the book. It is immediately followed by an excellent glossary of botanical terms which should make the descriptions understandable to the tyro. An introduction on Riviera vegetation by Mr. A. G. Tansley, is also very helpful. The book, though extending to some 250 pages, is printed on thin but tough paper, so that it will easily slip into the side pocket, a great convenience in the case of a work of this kind.

In Sun and Shade.—We have received a little twenty-page booklet† which might serve as a token of friendship to send to a flower-loving friend at Christnastide. It consists entirely of verse and reproductions of painting in colour by the author, no doubt a lady. The verses are unpretentious, but none the worse on that account and the little pictures quite attractive.

Oddments!—We have received for review a slender little volume called by the above-written illuminating title‡ and owning as author and compiler a Dr. Gilbert E. Brooke, at present Chief Health Officer, Straits Settlements. Largely in

* "Flowering Plants of the Riviera," by H. Stuart Thompson. Published by Longmans, Green and Co., 39, Paternoster Row, E.C.4.; 8vo. Now reduced to 7s. 6d. net.

† "Gardens in Sun and Shade," by M. Aumonier. Published by O. Anacker, Limited, 38, Soho Square W.; price 1s. 6d. net.

‡ "Oddments, Being Extracts from a Scrap-book," by Gilbert E. Brooke, 2, Fort Canning Road, Singapore; price not stated.

verse, but partly in prose, this whimsical little book is a welcome companion for odd half-hours. The reviewer could not at first see its special interest to readers of a newspaper devoted to gardening, but his eye presently caught an article beginning "Gardening is such an absorbing subject" which proved to be a description of the "cultural" and other peculiarities of *Clavus gallicus*—the French Nail! The very subtle humour of the author cannot, however, be well illustrated at second-hand. A short poem with the metre and very flavour of Longfellow's "Hiawatha" called "Dainty Dishes" is particularly well done, but it must not be assumed that all the oddments are facetious or even humorous. All are interesting reading, however, and, as was suggested before, this booklet, for it is little more, would be a welcome pocket companion for anyone at a loose end for an hour.

Hardy Fruits in North America.—The Macmillan Company of New York have just published an authoritative work on Hardy Fruits cultivated in North America.* The compiler, Dr. U. P. Hedrick, is "Vice-Director and Horticulturist" of the New York Agricultural Experimental Station. American readers of *THE GARDEN* who are interested in fruit culture should certainly procure this very comprehensive work. To readers in the British Isles it is chiefly interesting as shewing how entirely different are the varieties of Apples cultivated "across the Pond" from those ordinarily grown here. In the case of the Pear, on the other hand, the varieties grown are pretty much the same in both continents, though Bartlett, as the Americans call Bon Chrétien, is more popular "over there" than Pitmaston Duchess, which is the more useful variety on this side. The book is divided into eight parts, Part I being devoted to "Pome" Fruits—Apples, Crabs, Pears and Quinces; Part II Drupe Fruits—Apricots, Cherries, Nectarines, Peaches and Plums; Part III to the Grape Vine; Part IV to Brambles—Raspberries, Blackberries and Dewberries; Part V to Currants and Gooseberries; Part VI to Heath Fruits (mis-spelled "Health" Fruits in the Table of Contents)—Cranberries, Blue Berries and Huckleberries; Part VII to Strawberries; and Part VIII to Miscellaneous Fruits—Persimmons, Mulberries, Pawpaws, Elders, Highbush Cranberries, Buffalo-Berries, Goumis and Barberries, a chapter being devoted in each part to the botany of the section and in subsequent chapters very careful descriptions being afforded of each variety. Many varieties are illustrated diagrammatically, and there are sixteen plates, four of them excellently reproduced in colour. This is an admirably arranged work, quite destitute of verbiage. It might be taken as a model by authors desiring to impart information concisely.

EDITOR'S TABLE

From Messrs. Artindale of Nether Green, Sheffield, the Editor recently received some admirable trusses of *Primula obconica*. These shewed a very considerable and good range of colour, one or two of the deep crimson forms being especially noteworthy. Some of the fimbriated sorts were also very attractive. Quite by accident these flowers were seen by Dr. Macwatt of Primula fame, who was much "taken" with them. He especially remarked on the neatness of the "eye" in all those sent and said he was inclined to consider them the best "obconicas" he had seen. It is not sufficiently recognised how easy these plants are to grow.

* "Cyclopedia of Hardy Fruits," by U. P. Hedrick; 4to. Published by The Macmillan Company New York; price \$6.00.

BUILD ON A GOOD FOUNDATION

In planting a garden or an orchard, whether large or small, for pleasure or for profit, it is important to lay a good foundation.

This means thorough preparation of the ground, careful planting and, above all, healthy, reliable, well-rooted trees, of good constitution, of the right sorts on the right stocks.

Inferior fruit cannot find a profitable market. Good fruit can command one.

We specialise in fruit trees for Market Growers or Amateurs, and shall be pleased to give intending planters the benefit of over 40 years' experience in fruit growing.

Roses, Shrubs, Perennials and Alpines are equally well grown

HARDY PRIMULAS FOR GARDEN AND WILD

THERE are many gardens in which Hardy Primulas are held in no esteem in which, indeed, they are conspicuous by their absence. On light, dry soils there is much excuse for this neglect, at least as regards the many moisture-loving species, but any soil not absolutely devoid of humus will grow the various forms of our native Primroses and Cowslips to perfection provided advantage is taken of the shade of trees and shrubs. The value of coloured Primroses, particularly of the blue ones, is undoubted, and if their merits are not discussed at length here it is simply because, to do them justice would require a moderately long article.

Coloured Cowslips are not grown to a title of the extent to which their merits would seem to entitle them. In natural-looking colonies in the shade of shrubs they are exceedingly attractive. As they reproduce themselves freely from self-sown seeds, they should appeal to those very numerous garden owners who are compelled to curtail maintenance costs. Their comparative lack of popularity is almost certainly due to the fact that they do not shew to advantage on the show bench. No doubt they could be staged effectively if someone thought it worth while, just as the late Mrs. R. V. Berkeley set up coloured Primroses effectively.

There are many hardy Primulas which are quite happy wedged between stones in the rock garden and which require no more than an average amount of moisture. The florists' Auriculas are by no means enamoured of wet ground; indeed, the choicer varieties need culture under glass chiefly because of their propensity to "damp off" in the dank days of late autumn and winter. Some few species like a rather dry position, preferably in open woodland. This particularly applies to the *cortusoides* (*Sieboldi*) group, which includes *PP. saxatilis*, *Sieboldi* (many varieties), *Veitchii* and *lichiangensis*. *Primula saxatilis* is almost always met with in gardens as *P. cortusoides*, which is rare in cultivation. *P. saxatilis* is an equally good and effective plant, however, with lilac rose flowers

P. Veitchii varies considerably in flower colour from a rather washy, but not pale, lilac rose to a brilliant rosy purple nearing magenta. Despite the testimony of the late Reginald Farrer to its hardiness, this *Primula* withstands an average winter inland only in specially favoured situations. It is certainly more tender than most of the forms of *Primula Sieboldi*. *P. lichiangensis* is somewhat similar to *P. Veitchii*, but the foliage is stiffer and more robust, the flower-stems more rigid and erectly carried, and the flowers, which are a little smaller, have a conspicuous dark eye and

very distinct brown calyces. The colouring of the flowers, a deep rose, is also practically constant. This is a far hardier, more interesting and better plant than *P. Veitchii*.

The saxatile smooth-leaved forms of *PP. Auricula*, *viscosa*, *villosa* and *hirsuta* are easy enough in the rock garden. *Primula Auricula* itself is not so often seen in gardens as it should be. The leaves are mealy and the flowers a beautiful clear yellow. The plant is more compact and desirable when growing in a compost containing an abundance of lime, but it is by no means difficult in any really well drained soil. *Primula hirsuta* is, sad to say, usually called *P. viscosa* in gardens. It is a highly desirable species with bright rose or mauve flowers and the foliage clothed with yellow or tawny hairs. Overshadowed nowadays by many garden forms and hybrids, the best of the wild forms of the species are well worth growing. They are less formal and, if one may say so, more natural looking. *P. villosa* is nearly related, but the foliage is limper and the hairs are longer and darker and equally dense. *P. viscosa* (true) is generally listed as *P. latifolia*, which, indeed, is fairly good as a descriptive name. The flowers, which are carried on fairly tall stalks, are violet purple, and the whole truss hangs to one side. The broad foliage is greivish green in colour, lax in texture and has an objectionable odour.

The garden forms of *Primula hirsuta* (generally listed under *P. viscosa*) are almost all hybrids and are best referred to *P. s. pubescens*. They are all miniature forms in various colours of the garden *Auricula*, which botanically is now itself classed as *P. pubescens*, this name being reserved for all cross-breeds of the four species (or any two or three of them) already mentioned. *Primula Mrs. J. H. Wilson*, *P. The General*, *P. Mrs. Barclay* and a whole host more together with the beautiful white-flowered plants usually grown in gardens as *P. nivalis* and *P. helvetica alba* are all referable to *P. s. pubescens*. *P. viscosa alba* is occasionally met with, but there is a very beautiful pure

A FINE COLONY OF PRIMULA FRONDOSA.

white form near akin but with *P. Auricula* blood which should be referred to *P. pubescens*.

Primula marginata is another of the *Auricula* kindred, and one of the most lovely. It lifts itself above the ground on ever-lengthening woody "trunks" and in gritty soil spreads rapidly, soon forming an involved mat. The flowers are a very pleasing amethyst shade, but perhaps the principal charm of the plant centres in the foliage. Stem and furled leaves are swathed in golden farina, and the prettily notched expanded foliage is distinctly edged with it; hence the specific name.

The *farinosa* group of *Primulas* is represented in Butan by the beautiful Bird's Eye Primrose, *P. farinosa*, one of the most widely distributed of plants. Farrer considered it the loveliest of our native alpinists, but not everyone, we imagine, would agree with him. The rosettes of mealy foliage are exceptionally charming, however, and the flowers, which are carried in loose umbels, are, if not brilliant, exceedingly dainty and attractive. On page 587 we illustrate *P. frondosa*, which is the most robust of the *farinosa* section, and which will naturalise itself in any light, open, well drained soil.

Many of the moisture loving *Primulas* and certainly the most showy species, belong to the *Candelabra* section, that is, those in which the flowers are produced in whorls, "tier upon tier."

Primula japonica was the first introduced, and is still perhaps the best known, of the water-side or wet-ground *Candelabra* species. It is a robust species which under favourable conditions reproduces itself very freely from self-sown seedlings. There are so many bad forms about that it is well worth going to some trouble to procure really good ones. The typical plant is crimson—in a good form a rich velvety blackish crimson—but the plant is now procurable in a wide range of colours, including pure white with a rich golden eye. Many of the plants sent out as *P. japonica alba* are of a dirty buff colour usually tinged around the eye with rosy shades and altogether abominable. There is a brilliant deep salmony rose form which is very desirable, and there are other good rose forms of softer colouring.

Primula pulverulenta is by many considered little more than a mealy stemmed form of *P. japonica*. To those who know the two plants well, however, there is an immense difference, and it must be admitted that *P. pulverulenta* makes the older plant look very "cablagic" and commonplace. The mealy stems of *pulverulenta* tower much higher than those of the Japanese, the flowers are larger and handsomer and are better spaced, and the spike has more tiers and is more spiry. The spike of *P. japonica* has a tendency to be round headed. The difference between the two plants is clearly shewn in the pictures illustrating them on this page. A solitary plant of *P. japonica* may be seen near the water-side in the picture of *P. pulverulenta*. Both plants like wet ground yet are their cultural requirements not precisely similar. Whereas *P. japonica* will flourish in not too dry woodland and luxuriates in any rich garden soil quite away from water, *P. pulverulenta* is less accommodating in that respect. It may be grown under such conditions certainly, but does not give of its best and is very prone to attack by red spider. *P. japonica*, on the other hand, is not an aquatic, and if submerged for any length of time through water flooding, will perish. The more recently introduced species will tolerate, even appreciate, such flooding, and will grow well in wet places in quite dense shade even under the drip of trees, where *P. japonica* would fail. There are two pink forms of *P. pulverulenta* in existence. One, a very soft, almost blush pink with a yellow eye,

PRIMULA PULVERULENTA IN THE DELL.

THE YELLOW TINGED APRICOT PRIMULA BULLEYANA.

PRIMULA JAPONICA IN THE WILD.

MICHAELMAS DAISIES

The composition of my collection.—Climax for ever.—A rapid run through the Novi-Belgii.—Oh! what a surprise!—Smaller fry.

was certificated as Mrs. R. V. Berkeley. The other, which is more robust in habit, has salmony pink flowers and a rich orange eye, and is perhaps the most beautiful of hardy Primulas. When offered by nurserymen at all it is usually as Mrs. R. V. Berkeley, but it is absolutely distinct from the true stock of that variety.

Primula Bulleyana can be described very briefly as a rather late-flowering P. japonica with orange yellow flowers with rather an apricot tinge. They are, however, much more yellow in colouring than Rose Lady Hillingdon, for instance. Primula Beesiana is still later flowering, and therein lies its chief value. It is, however, a less desirable species than either of the three last mentioned. The flowers are reddish purple. The best coloured forms have more than a hint of magenta; the others are dowdy in the extreme.

Primula Cockburniana is a much smaller plant, growing only roins, or 1ft. tall to the top of the developed inflorescence. It has flowers of a fiery coppery orange colour, but being of little better than biennial duration, chiefly appeals to the gardener on account of the many attractive hybrids of which it is one parent. It crosses exceedingly readily with P. pulverulenta to produce, according to the way the cross is made, the plants known as PP. Lissadell Hybrid and Unique. Both are of a curious mahogany colour lit with salmon and extraordinarily brilliant in sunlight. Lissadell is freer to flower, rather paler and smaller than Unique. By crossing P. Cockburniana with one of the pink P. pulverulenta forms, paler shades are produced, but most of them are rather washy in colour and undesirable. All these Cockburniana × pulverulenta crosses are fertile, and there is consequently a practically endless series of forms between the two parents. Some of the very finest dark forms of P. pulverulenta are produced as recessives in this intercrossing. They accordingly breed true. A form of P. Cockburniana is produced in a similar way, which is even fierier in colour and more robust-looking but less free-flowering. This is a better perennial than the plant as introduced.

With PP. Bulleyana, and Beesiana Primula Cockburniana crosses also, but not so readily as with P. pulverulenta. Some of the Beesiana hybrids are very striking and beautiful, others quite valueless. The same remark applies to the hybrids between PP. Bulleyana and Beesiana, for the two species intercross readily enough.

Primula Poissoni is another of the Candelabra section, but very distinct. It has smooth glossy, rather flaccid foliage and whorls of blossom of an unattractive shade of magenta purple. An easy doer, it likes partial shade.

Other wet-land Primulas include the well known but admirable P. rosea, P. involucrata with bluish white flowers; P. Wardei, somewhat similar, but of a lively, if variable, pale violet colouring (this is the plant usually listed as P. sibirica); it is peculiarly valuable because so often in flower); PP. sikkimensis, chionantha, helodoxa and Parryi. Primula sikkimensis with its nodding pale sulphur yellow cowslip-like flowers is a general favourite but a short-lived plant. The creamy white P. chionantha is related but more robust-looking, and will probably prove more truly perennial. Primula helodoxa really belongs to the Candelabra section, but differs from other species in the section rather considerably. It is a tall species, very easy to grow in moist ground, and the flowers are a pleasing shade of soft but rich yellow.

There is a multitude of interesting species even now not mentioned, but, except for the members of the capitata group whose confused nomenclature we hope shortly to tackle, few are of much garden value.

IT is very possible that many people have grown a larger collection than I have, but I can safely say that even if they had had ten times the hundred and twenty-five varieties that I have had they could not have given them more pleasure nor provided them with more interest. I want to make plain my limitations. There was none of the Amellus section. These somehow seem only half Michaelmas Daisies on account of their stature and their flowering period. There was not a single example of a Novæ-Angliæ, because I do not care for them so much as I do for the Novi-Belgii and my garden is not elastic. I have very few doubles, again for the last-named reason. They do not

consideration of garden ornament, the consideration of fine graceful habit, the consideration of a perfectly delightful flower and the consideration of grace in a vase—let alone that of being nearly mildew-proof, no other Daisy is quite what Climax is. I take my hat off to Edwin Beckett, its raiser; and after this act of homage I pass on to deal with some of those of this splendid race which have "found me" in 1922. King Albert is a tall man with a wide outlook on affairs. King of the Belgians is his counterpart in a Michaelmas Daisy. It is very tall, very handsome, and its great big rosy lavender blooms are "just right." They are not a bit out of keeping, as are the soup-plate blooms of

MR. EDWIN BECKETT'S MICHAELMAS DAISIES.

appeal to me at all, and one has to cut something out. These facts will explain what otherwise many would think strange omissions in the list. Can I call any one "mea rosa"? any one "the apple of my eye"? any one "the pink of perfection"? I think I can; at all events if I were tested by being told I might only grow one Michaelmas Daisy in my garden, it would not be the magnificent towering King of the Belgians with its great big flowers; it would not be the lovely soft pink Louvain; it would not be the beautiful bright rose General Leman or the rather softer clear-toned Hilda; I would pass over the hair-like petalled Miss Eisle; even the Edwin Beckett that came from Wells and is not a deep blue cordilolius, would have to be given—very grudgingly I own—a reluctant cold shoulder.

"The great Emathian conqueror bid spare
The house of Pindarus, when temple and tower
Went to the ground."

So would I beg for the life of Climax if all my beauties had to be destroyed by a cruel fate. Taking one consideration with another—the

much shorter Bruges, although the extraordinary floriferousness of this last compels the attention of even the least observant. A variety of somewhat similar colouring, but with no rose tint in the mauve, is Brussels. It is almost a true lavender, but these shades are very difficult to describe with accuracy when there are so many different varieties whose colouring runs very much one into another. Blue-toned helios of the first water include Climax and also Feltham Blue. This last has a very deep yellow eye and, what after all is to me a most valuable asset, it is a clear clean-cut flower. Would you like the "wee modest crimson tipped flower" if its centre were all blurred and half its tiny florets seemingly undecided if they were to dress for the centre or the outside? It would not then very much matter if

"Stern Ruin's plough-share drives elate
Full on thy bloom."

In fact, there are some Michaelmas Daisies which I would dearly like to see sharing that fate. The greatest offender in my collection is not contented with putting up a much blurred central

flower, but there are an innumerable number of smaller ones tightly packed all round it *à la* hen-and-chicken Daisy. I do not know its name. I wish I did so that I might fence it with a notice board "keep off." It came to me under the name of Mrs. Twinan, but as it is a deep helio and no more pink than an Emperor Daffodil, it cannot be that variety. I know now why I saw a well known would-be purchaser look under the flower of a fine white seedling that he was asked to consider with a view to a purchase and why that wise head shook as if it would come off after he had inspected it. It had the mark of the beast writ large behind each central flower. Careful man! Keeping in a rough way to colour, no one should be without Edith Goodwin. It has such a splendid habit—feathered with subsidiary sprays all down to the ground; clean-cut flowers not far off the shade of old Attraction. I never seem to remember any pinks in olden days. There cannot have been many, but now we have Louvain, Lady Lloyd, Thelma Perry, Mrs. Wheeler Bennett, Mrs. H. Morris, Sunset, Pink Perfection and the spidery petalled Ethel Ballard. These far from exhaust them, but I do not wish for any more. Of these give me Louvain, tall, branching, reminding one in a distant way of Climax, and of a lovely soft colour which keeps pink to the end; Sunset next, later to flower and shorter in stature than Louvain and more of a typical Michaelmas Daisy in its habit; as a third, Lady Lloyd, paler in the centre of the flowers than at the outside, which adds to their charm, early to bloom and exceptionally free.

How difficult it is in many cases to say where one begins and the other leaves off. Heat and cold, for example! How about pink and rose? There must be a watershed down one side of which go the pinks and down the other the roses, but it is to me a *terra incognita*. Hence one is a little uncertain about one's labels, and passing from pink to rose is rather a ticklish job. However, General Lemna is a rose, and it is a rose which keeps rose to the end. This, however, is where that much puffed-up variety Brightest and Best signally fails. Dainty, now, with similar semi-double flowers, does keep rose all its life, and is far brighter and more pleasing if it is not so tall and has rather smaller blooms. Hilda, although the edges of its petals incurve, which is a trick I do not at all like, nevertheless at a distance stands out as a really beautiful shade of rose. It is fairly tall, and I have it down as of a nice branching habit. This is, unfortunately, the failing in the case of Sirius, which, were I to judge it by its flowers alone, would almost be my favourite rose. It has such a large, attractive centre, round which the bright ray florets are so orderly arranged that the whole effect is exceptionally smart. It is, alas! one of the "mop-heads," a name I have coined to express the type which bears all the blooms in a sort of more or less flat mass at the top of the plant, as we get, to take a second example, in Reverend Nunn, the variety which, of all the many perennial Asters I know, may be called blue, not, of course, a blue like Forget-me-not or Tecophilaea blue, but not bad for a Michaelmas Daisy.

Collection growing is wonderfully exciting work if you have a good proportion of unknowns among those you have got together. Do try it if you never have done so. Colour scheming is a dull job compared to collection growing, in my opinion, but *chacun à son goût*. Among my most pleasant surprises were Magnet and Edwin Beckett, as I got it from Amos Perry. The best of these is a rich dark helio several tones deeper than Belgian Queen. It is a true counter part of Climax in its habit of growth, but, like

Belgian Queen and The Queen (another good Michaelmas Daisy), it is late to come into bloom, which makes it of additional value. The individual flowers are 2½ ins. to 3½ ins. across. Perry's Edwin Beckett I am very much inclined to put *proxime accedit* to Climax. I hardly dare begin to write about it and sing its praises. It is a mid-season bloomer—a good 5ft. high—the much-branched stem all crowded over with medium-sized pale lavender blooms, and as each one has a nice little pedicel of its own, the result is that the whole *tout ensemble* is lightness itself

"The rose that all are praising
Is not the rose for me."

No, Mr. Baily, I can only say "not always." Whites seem none too plentiful. Sam Banham has improved on acquaintance, but I, personally, still like Perry's White the best, although Maid of Colwall runs it somewhat close. For vases Nina Redman is very charming. It is so light-looking and graceful and, being one of the early birds of the race, we give it a double welcome.

Now I hear someone thinking aloud, "Why the fellow has never mentioned any of the smaller fry. Does not he care for them?" On the whole I do not think I do, but there are *many* exceptions. Little Bo-Peep, which was a present from Mr. Vicary Gibbs, is a real topper—Photograph, Ideal and the rest of you cordifolius people, you must retire. Little Bo-Peep was the universal favourite. Its wealth of small delicate lavender blooms appealed to everyone. As a good companion to the above why not the old Diana? Where does this differ from cordifolius elegans? I have them both, or as it seems to me, I have the same thing under two names. If this is correct, Diana has been before the public for the last twenty years and still goes very strong. "Time!" If, Mr. Editor, you think all this has been interesting, may I beg a little more space another week still further to unburden myself of some of the things I would like to say? I make my appeal as a devoted slave of the "slave" of our autumn gardens. Will anyone challenge this?
JOSEPH JACOB.

THE HERBACEOUS PHLOXES

Is their Place the Herbaceous Border?

I HAVE often thought it rather strange that if the average gardener is asked for a list of plants for the herbaceous border, he almost invariably starts by mentioning "Phlox," by which, of course, he means the erect-habited decussata and suffruticosa forms. Unquestionably the best results are obtained with these when they have a border allotted to them. These Phloxes are rather shallow rooting, very gross feeders and intolerant of drought. If planted in the herbaceous border special attention must be given to them most seasons, but they are easier to attend to and do better when given quarters to themselves. Given an abundance of moisture at the root, they do not object to sun-heat, although the salmon

shades fade badly in sunlight. They are less troublesome to grow, however, in a border with a north or west aspect and, preferably, backed by a wall. Hedge roots abstract much nutriment from the soil and, what is perhaps even more important, they render it almost impossible to keep an adequate supply of moisture in the soil.

Phloxes should be replanted at least every two years. Growers for exhibition usually replant every season. It is quite possible to grow fine spikes from divided plants if care is taken only to retain the vigorous outer portions of the clumps. Propagation from cuttings is, however, quite easy, and many people will consider Phloxes as worthy of careful

A BORDER OF PHLOXES AT NEW PLACE, LINGFIELD.

TREE AND SHRUB GARDEN

THE HAWTHORN FAMILY.

propagation as *Chrysanthemums*. Who nowadays propagates the Queen of Autumn by dividing the stools? The plants offered by nurserymen are almost invariably from cuttings, so that the amateur makes a good start and is set a good example!

Cow manure is generally advised as a fertiliser owing to its moisture-holding property, especially on light soils, but good horse dung is excellent. Wakeley's Hop Manure is exceedingly valuable for its moisture-holding properties and is, of course, a fertiliser as well.

It makes an excellent mulch for use in droughty weather, but lawn-clippings or other material may, at a push, be pressed into service for this purpose. The surface should be broken with the hoe before the mulch is applied, but only the top inch should be broken, or damage will be done to the spreading roots.

To be effective the plants should be set out in groups of a size proportionate to that of the border. Each group should consist of at least three plants; a dozen or eighteen will hardly be too many for a large border. Eighteen inches between the plants is a suitable distance. A certain amount of thinning out of the weaker growths is essential if the best results are to be obtained, this being especially the case where plants more than a year old are concerned.

Phloxes certainly do well by the waterside in places where a constant level of the water is maintained, so that, never flooded, their roots always have access to an abundance of moisture. I should not, myself, plant them there, because I do not think their habit of growth lends itself to such planting, but that is purely a matter of taste.

The question of varieties, now that there are so many sorts in cultivation, is rather a difficult one, but the following are all excellent for garden decoration.

For the garden I have yet to see the white sort which surpasses the old *Sylphide*. *Frau Ant. Buchner*, however, is the one generally grown, and *Tapis Blanc* is useful for the extreme front of the border. *Mauve Queen* is probably the best mauve; it has a white eye, but in slightly different colouring, *Antonin Mercie* is good. *Mr. Jacob* has an excellent selection of really bright border sorts in last week's issue. *George A. Strohlein* and even the old rather small-flowered *Coquelicot* might be added to these as desirable. That grand old sort *Selma "J. J."* mentions among the dwarf ones. Another admirable cream pink is *Hanny Pfeleiderer*. *Violet Phloxes* are in demand for some purposes, but at present the quality is indifferent. Perhaps the best is *Le Mahdi*, but there is immense room for improvement in this colour. W.

THE hot summer and autumn of 1921 ripened the wood of many trees and shrubs so thoroughly that they flowered more freely than usual this year, and those that flowered early, while the weather was good, set very heavy crops of fruit. This was the case with the Hawthorns, and rarely

the best species and varieties for present planting.

Many people pin their faith to the double-flowered forms of the common Hawthorn, and they are certainly very beautiful in May, but they have one great defect, they produce no fruit. Possibly the best of the doubles is *Paul's Double Scarlet*, a variety with rich, bright red flowers, but *alba plena* and *candida plena* with white, and *rosea plena* with rose-coloured flowers are also good. These are all varieties of *Crataegus Oxyacantha*. Other varieties of the same species are *coccinea* with single red flowers, *coccinea pendula* of weeping habit and *fructu-luteo* with yellow fruits. Of the other form of the common Hawthorn, *C. monogyna*, the following varieties are specially worthy of note: *aurea*, yellow fruits; *granatensis* and *fusca* with large red fruits; *pendula* with weeping branches; *præcox*—the *Glastonbury Thorn*, which blossoms in mid-winter—and *stricta*, remarkable for its stiff, erect branches, which have the same effect as those of the *Lombardy Poplar*.

There are many other species that are equally beautiful in flower, and more so in fruit, for the fruits are larger and brighter coloured than those of the common Hawthorn. *C. coccinea*, a North American species, is one of the best known. Forming a tree 20ft. to 25ft. high with a large and wide-spreading head, it is one of the most regular of all Thorns in flowering and fruiting. The flowers are white, $\frac{3}{4}$ in. across and produced in large, flat heads. The flowers are followed by pendent bunches of bright red fruits, each fruit being $\frac{1}{2}$ in. in diameter. They are ripe in September. There is a variety *rotundifolia* which is not so well known. It forms a smaller tree but fruits quite as freely. *C. mollis* is another very beautiful Thorn from North America. In flowers and fruit it is very like *C. coccinea*, but differs by the hairy character of the leaves. *C. coccinioides* is one of the newer species that has affinities to *C. coccinea*; its fruits are darker coloured, but borne very freely.

The *Washington Thorn*, *C. cordata*, is easily distinguished from all others by its rather small leaves and late flowering period, the white flowers being at their best in July. The fruit is small, scarlet, ripens late, and often remains on the tree throughout winter. It grows 30ft. high and is a native of the Eastern United States. *C. punctata* is very distinct by reason of its large, prominently ribbed or veined leaves and large spotted fruits. The fruits of the type are deep red, $\frac{1}{2}$ in. to $\frac{3}{4}$ in. long, and dotted over with small brown spots. There is a variety *xanthocarpa* in which the fruits are yellow with brownish dots.

C. Azarolus, a native of the Orient, is a very remarkable Thorn, not so much by its white flowers as by its fruits. The fruits are about 1in. in diameter, apple-like, yellow, orange, red or white; fleshy, sweet and edible. Another Thorn with large edible fruits is *C. tanacetifolia*. This has very hairy leaves and shoots, short stiff branches, white flowers and yellow fruits 1in. in diameter which bear green, leaf-like bracts on the surface. It is a native of Asia Minor and Syria. In leaf *C. orientalis* is rather like *C. tanacetifolia*, but the leaves and fruits are smaller, the fruits also vary in colour from yellow to orange and red.

C. sanguinea, from Russia and Siberia, bears rather small, glossy, bright red fruits, and is a good kind to select. *C. prunifolia* is often regarded as a hybrid between *C. Crus-galli* and *C. macrantha*. It forms a bushy-headed tree

FRUITS OF THE COCKSPUR THORN, *CRATÆGUS CRUS-GALLI*.

have they bloomed so freely as they did in May and early June, or borne heavier crops of fruit. The country has rarely been more beautiful at Whitsuntide than it was in 1922, for every hedgerow and isolated Thorn bush was covered with flowers, whether it happened to be in a highly cultivated garden or a wilding on hillside or common. At the present time these same bushes are covered with red fruits.

Nor is it the common Hawthorn alone that has blossomed and fruited so profusely, for the same thing has happened with cultivated varieties and exotic species. The old theory of heavy crops of Hawthorn and Holly berries being sure signs of a hard winter is still credited in some quarters, but the theory cannot be substantiated by fact, for the flowering and fruiting of trees and shrubs is determined by the weather that has gone before, not by what is to come, and a hard and cold winter is just as likely to follow a poor as a good crop of fruit.

As a good deal of interest has been created in the *Crataegus* family during the last few months, it may be wise to direct attention to a few of

20ft. high, and bears white flowers and deep red fruits freely, but is perhaps most remarkable by reason of the rich autumnal tints of the foliage, which embrace many shades of red, yellow, orange and bronze. *C. mariantha* is an Eastern North American species which bears very attractive, glossy, crimson fruits. *C. Crus-galli*, the Cockspur Thorn, so called by reason of its long, strong spines, bears white flowers and crimson fruits; the leaves have attractive autumn colouring. *C. durobrivensis*,

one of the newer American Thorns, bears bright crimson fruits rather more than half an inch in diameter. *C. Carrièrei* should be in every collection on account of its late flowering and fruiting. The flowers are white, nearly an inch across and produced in flat heads 2ins. or more in diameter. The fruits are orange red, 3/4in. in diameter, and ripen in November. There are several Thorns with black fruits, such as *C. nigra*, *C. chlorosarca* and *C. Douglasii*, but their fruits are less attractive than those of other species.

C. Douglasii, however, is very beautiful in autumn by reason of the bright tints taken on by the foliage.

The Thorns are easily grown in any good garden soil. They should receive a little attention in the way of pruning while they are young in order to induce height instead of lateral growth, but it is not a good plan to remove large branches from old trees, for this may set up disease, resulting in the loss of a favourite specimen.

W. D.

A SELECTION OF BORDER CARNATIONS AND CLOVES

THE following list of varieties, which includes some of the latest introductions, comprises the best varieties in the different colour sections. All the sorts mentioned can be relied upon to give satisfaction for garden decoration, and almost all of them are suitable for exhibition purposes.

GRENADE is easily first among the scarlets. It is a brilliant colour and does not scald in the hottest sunshine. It is a large flower, sometimes attaining a diameter of 4ins., yet its petals are the right size for expanding in wet weather. It has a fine border habit.

VELDFIRE is another fine scarlet self, not quite as brilliant as Grenadier, and not as reliable in wet weather. At its best, however, it is a very fine variety with a sound calyx.

GLOW-WORM.—This is a real dwarf scarlet of perfect size for border work, very floriferous and the flowers carried on wiry stems. One year plants have had as many as 120 blooms at a time.

SCARLET CLOVE is one of the finest of the new Cloves. It is a colour that Mr. James Douglas has been working on for years, and he has at last succeeded in producing it with the true Clove habit. It is not a brilliant colour like Grenadier, but a pleasing shade of reddish coral. It has a very strong aroma.

FUJIVAMA is a deep red rather than scarlet. It sometimes shews white ticks in the colour. It is a good exhibition variety.

CRYSTAL CLOVE is a peerless white Clove of fine shape and habit and very fragrant.

WHITE CLOVE.—Of strong dwarf habit, this very powerfully scented Clove is ideal for border

work. If left undisturbed it makes a huge plant the second season, when its freedom of flowering will be a revelation. It is possibly the most highly perfumed Clove to date.

GOLDFLOCKS is a really fine apricot self for border cultivation. It is a very pleasing colour and the habit is grand.

BOOKHAM SALMON.—This is a very beautiful salmon pink, and although the flowers are very large, it has a splendid calyx. It is a fine variety of good constitution.

SALMON CLOVE.—Like the above, this variety changes to a lovely shade of salmon pink after opening. Sometimes, however, it opens without scent, but after a few hours develops a strong Clove fragrance. This is a peculiar characteristic.

STIRLING CASTLE and **MOONBEAM** are two of the best yellows of their type, and the vigorous

FANCY CARNATION STEERFORTH.

THE FRAGRANT KING OF CLOVES.

HARDY PLANTS TO REPLACE BEDDING

(Continued from page 526.)

THE great white silky cups, golden stamened, of *Romneya Coulteri* against the dark, rather greyish green foliage are very effective, but it is advisable to establish this plant near the foot of a sun-baked wall, otherwise it is not sufficiently reliable in cold seasons to merit a place in the garden immediately adjacent to the house.

Of shrubs more properly so described which may advantageously be employed, there are

are innocuous in colouring) and the inevitable *Madonna Lily* (*L. candidum*). The beautiful *speciosum* varieties and the even grander *auratum* are, of course, delightful anywhere, but they can be considered permanent denizens of few British gardens. Even where they succeed it is rarely possible to provide for them properly in the flower garden. They like their "heads" in sunlight and their "heels" in shade.

For autumn effect Michaelmas Daisies are

habit and sound calyx of *SUNSHINE* are two of its best points. The latter is a good variety for the border.

ROBIN GREY is a fine border variety of very robust habit. It is a lavender grey.

BOOKHAM BELLE is a lovely fancy, canary yellow with heavy markings of lavender grey and lighter stripes of soft apricot. It is a very large flower of perfect form and sound calyx and it is also a strong grower.

KING OF CLOVES is the best dark Clove yet produced. It is a glowing shade of deep purplish crimson. Besides having a very vigorous habit, the flower-stems are very rigid and the calyx is non-splitting.

MARGARET KEEP.—A dainty shade of blush pink with the old Clove scent very pronounced. One of the finest of the newer Cloves.

MARECHAL NILL.—An appropriately named variety, for the colouring of the well known Rose is practically reproduced in the Carnation. The large blooms are of fine substance.

STEERFORTH.—A fine flower of dainty colouring, a white ground edged and flecked with a deep shade of crimson. It has the Clove scent.

CORALLINA.—A delicate shade of rich coral pink which is particularly beautiful under artificial light. It is a flower of fine form and good habit.

CLARET CLOVE.—A crimson claret coloured Clove of very strong habit with a perfect calyx. It is very floriferous and powerfully fragrant.

KELSO is unique in colouring. In the young flowers it is a purple-grey on a golden red ground, afterwards changing to heliotrope on soft apricot. It is a perfectly formed flower and good for either exhibition or the border.

MELANIE is a magnificent apricot self of fine border habit.

PALADIN.—This is a beautiful fancy, a finely formed flower with an edge and pencillings of purple on a yellow ground. It is a good border variety.

PURPLE CLOVE.—This is the finest of its colour yet produced. It has strong habit and good border form. The perfume is very pronounced.

PEARL CLOVE.—A delicate shade of pearly lilac rose. It is a strongly scented variety, and the habit and constitution are quite good.

SIR BRUNETTO CLOVE is one of the best of the dark varieties. It is a rich deep maroon, at times almost black. It has a grand border habit, and the blooms are borne on strong, rigid stems.

BLUSH CLOVE is another delicately coloured variety with an exceptionally heavy perfume. It requires no staking as the flowers are carried on very strong, rigid stems, which stand erect above the foliage.

MRS. HAWKSBEET is a very beautiful fancy, lightly flecked and barred with bright rosy crimson on a pure white ground.

SIR DOUGLAS HAIG is another fancy of the best form. It is heavily marked with crimson maroon on a white ground. It has a splendid border habit.

LOYALTY is regarded by many as the finest orange apricot in existence. It is a fine variety for the border, having a strong habit, rigid stems and a good calyx.

In addition to the above the following can all be relied upon: *Alice Byron Stewart*, buff, edged and marked rose; *Centurion*, yellow with scarlet markings; *Cleopatra*, rose madder with light scarlet pencillings; *Ironsides*, buff, marked and suffused with deep rose; *Liberté*, rich yellow with heavy markings of maroon and crimson; *Linkman*, yellow with heavy scarlet markings; *Melton Prior*, one of the richest coloured fancies, yellow, heavily marked with bright scarlet; and *Pasquin*, yellow, edged and flushed with rosy lavender

NORMAN LAMBERT.

SNAPDRAGONS, CAMPANULAS AND GREY FOLIAGE PLANTS IN A PAVED GARDEN.

Lavender, Rosemary, some of the smaller-growing Veronicas and many species of Southernwood. Both tall and dwarf Lavenders are available. Of these latter probably the *Munstead* Variety is the most desirable. It may be used for edging beds in a similar manner to *Box* if such edging is required. *Veronica Autumn Glory* is an effective semi-prostrate sort, but *V. glaucophyllum*, *pinguifolia*, *cerulea glaucescens* and even the quaint heath-like *V. loganoides* have their value. Of Southernwoods (*Artemisia*) the nomenclature in nurseries is not too reliable, but in addition to the true Southernwood, *Artemisia Abrotanum*, *AA. arborescens*, *Stellariana* and *margaritaceum* are some of those valuable for silvery foliage. The herbaceous *A. lactiflora* is also quite a useful plant with its creamy flower spikes.

Lilies assuredly produce a fine display when in blossom, but they need using with caution for two reasons. In the first place, their glory is comparatively short-lived; and, secondly, choice things such as these should not be used with too prodigal a hand. They shew to best advantage when contrasted with flowers of lesser pedigree. Many Lilies are too difficult in colouring for close association with other plants; some, on the other hand, are both charming in themselves and excellent as neighbours. Such are *Lilium testaceum*, an admirable and easy-doing hybrid Lily with flowers of pinkish buff; *L. Henryi*, like a stalwart soft yellow *L. speciosum*; *L. Martagon album* (or even *Martagon* itself, for its flowers, if not brilliant

invaluable. Some of the taller varieties may be included in the permanent planting, but it helps the general effect greatly if plants of the *Amellus* section and other dwarf varieties are grown in a reserve garden and lifted in autumn to fill up blank spaces. The related *Erigerons* are also useful, and some of them lift quite well if they are kept carefully staked as growth proceeds.

Some of the smaller Torch Lilies (*Kniphofia*) are very free-flowering and attractive, and their erect spires and rather grassy foliage give needed diversity, but care must be taken to select suitably coloured varieties. There are so many sorts nowadays, of which any one nurseryman stocks but a small proportion, that the best advice we can offer is to see the plants in flower and select them. Those with soft yellow and coral tones are quite innocuous.

The glowing blood crimson of the Cambridge Scarlet variety of the False Bergamot, *Monarda didyma*, is valuable where it flourishes. It likes a fairly light sweet loam. Of *Rudbeckias* the old *speciosa* (*Newmanni*) is specially valuable as giving a fine mass of colour, but the tall and handsome-foliaged *R. maxima* has more individuality and charm. *Rudbeckias* are particularly valuable for rather damp corners; they will not tolerate drought. That dwarf and brilliant *Helenium*, *H. pumilum*, and its variety *magnificum* are also unhappy in droughty conditions, but good cultivation and a fair amount of humus will usually suffice to keep them "happy."

There are many spring-flowering plants which may be included, mostly with pleasing foliage, to form a background to summer-flowering things. *Aubrietia*, *Alyssum*, *Phlox subulata* (for light, dry soils) and some of the Mossy Saxifrages may be taken as typical. Of the last mentioned *Wallacei*, *trifurcata* *ceratophylla* and all the true *moschata* forms, such as *S. m.*

atropurpurea and *S. m. laxa*; the last-named plant is identical with the true *S. Rhei*. *S. Rhei* of gardens, however, is almost invariably a rather pretty pink mossy hybrid.

No permanent planting can give quite the solid blaze of colour produced by "bedding out" and keep it up. Anyone whose taste calls for such effects must be content to use bedding plants.

LATE AUTUMN FLOWERS AT VINCENT SQUARE

THE dense fog which enveloped London and the suburbs overnight and throughout the early hours of November 14, resulted in a small Show at Vincent Square, Westminster, and the attendance was smaller than of late. But those who braved the weather were amply compensated by the quality of the exhibits in the hall. In view of the annual show of the special society later in the week, Chrysanthemums formed an important section. Mr. H. J. Jones excelled himself with a superb group and incidentally won his seventh gold medal of the year and, what no doubt pleased him even more, received the Special Congratulations of the Council for his great display. Baron Bruno Schröder, whose name is so closely associated with Orchids of great merit, sent an attractive group of Chrysanthemums of the highly decorative *Caprice du Printemps* type. Messrs Keith Luxford and Co. also had a valuable display of Chrysanthemums, but as these and the others are to remain for the special show, we reserve our comments.

Although not great in numbers, Orchids were of particularly high quality. Baron Bruno Schröder had a unique group of *Calanthe Harrisii*. It was a very large collection, arranged with great skill and taste and each plant was a perfect specimen, bearing tall spikes of milk-white flowers very slightly flushed with rosy purple. A gold medal would not have been too high an award for this superb group, but Baron Schröder received a silver-gilt Flora medal, while the coveted silver-gilt Lindley medal for the exceptional skill he has shown in cultivation, goes to Mr. Shill, the Orchid grower.

Sir Jeremiah Colman sent a small but choice collection of *Cattleyas* and *Brasso-Lelio-Cattleyas*. *Cattleya corulea* was daintily charming and *Brasso-Lelio-Cattleya Antoinette* was of gorgeous colouring.

Carnations were particularly bright and good. The vivid colours of *Lord Lambourne* and *Red Ensign* in the group by Messrs. Stuart Low and Co., who also massed their new *Eileen Low* and *White Pearl*, was welcome on the raw, foggy day. The deep rose pink *Mary Allwood* diffused pleasing fragrance even under the unpromising conditions. Messrs. Allwood Bros. had several vases of the fancy Carnations, which are fast increasing in popularity, and, while these do not make the colour display of the selfs, they are very fascinating. The free-flowering *Marian Willson*, *Benora* and *Eastern Maid* were prominent examples. In Mr. C. Engelmann's collection we noted in *Arnos Grove* a very uncommon fancy of red and mauve-violet shading.

There was a fresh trade exhibitor in Mr. E. H. Ganser who, we understand, intends regularly to contribute large collections, principally of greenhouse plants. His first exhibit was a very meritorious one of *Primula obconica* of an excellent strain; floriferous plants of *Cyclamen* and greenhouse Ferns. Among the last named were some beautiful plants of the billowy *Nephrolepis exaltata Marshalli compacta* which appears to be too

delicate for everyday use and yet is a splendid room plant.

Some vases of splendid Violets were shown from the Hayden Violet Grounds, Blandford. These

APPLE JOY BELLS.

were *Princess of Wales*, exceptionally robust and fragrant.

An uncommon but intensely interesting exhibit was the large collection of water-colour paintings of U.S.A. native plants on behalf of Miss Mary E. Eaton of the New York Botanic Garden. These were dainty, but most faithful, representations of specimens of a great number of plants.

Fruit was represented by collections of Apples and Pears by Sir Chas. Nall-Cain and Messrs. J. Cheal and Sons, and Cider Apples and Pears by Messrs. H. P. Bulmer and Co. The private collection was the largest and was characterised by the brilliant colour. The outstanding dessert Apples were *Paroquet*, *Baumann's Red Reinette*, *The Houblon* and *Orange Pippin* and among the many culinary fruits the useful *Mère de Ménage* and *Peasgood's Nonsuch* were especially fine. The Pears included *Conference*, *Pitmaston Duchess* and *Beurré Bachelier*. Messrs. Cheal's Apples were also of high quality, such sorts as *Christmas Pearmain*, *Adam's Pearmain*, *Baxted Favourite*, *Cox's Orange Pippin* and *Morris Green* were perfect examples of dessert Apples.

The Cider Apples were in boxes containing a couple of dozen or so fruits and several of the varieties were very attractive. *Kingston Black*, *Foxwhelp* and *Dymock Red*, for instance, were very attractive in their high colour, while *White Norman* and the small yellow fruits of *Eggleton Styre* were of uncommon appearance. The Perry Pears were *Aylton Red*, *Blakeney Red* and *Butt*.

NEW AND RARE PLANTS.

Carnation Eileen Low.—Already the value of this novelty has been realised by the show-attending public and we have on several recent occasions commented upon its grace and beauty. It is regarded by the raisers as being the most perfect of all the salmon pink varieties. From the plants we should judge it to be a "good doer" and very free-flowering. The flowers are large and of good form. Award of merit to Messrs. Stuart Low and Co.

Carnation Master Michael Stoop.—This is a rather large flowered perpetual Carnation of very uncommon colouring which may best be described as a rich rose-cerise fading to old rose with a suggestion of salmon pink. It appears to be a free-flowering variety, the blooms are compact and under better conditions it is probably fragrant. Award of merit to Mr. G. Carpenter.

Carnation The Hon. Neta Weir.—This may be described as being a deeper coloured *Enchantress Supreme* with all the good qualities of that popular variety. Shewn by Messrs. Stuart Low and Co.

Chrysanthemum Miss M. A. Hunter.—A well formed single variety of rather more than medium size. It has several rows of broad, yellow petals which are lightly stippled with bronze towards their tips, which are slightly recurved. Award of merit to Mr. G. Carpenter.

Chrysanthemum Oriole.—This is another very decorative single-flowered variety of large size. The narrow, rolled petals stand out straight, giving somewhat the same uncommon effect as seen in *Rayonante*. The colour is a good yellow and we anticipate a future demand as a variety for decorative purposes. Award of merit to Messrs. Keith Luxford and Co.

Chrysanthemum Radiant.—This handsome single-flowered Chrysanthemum which, for some unaccountable reason did not find favour with the Floral Committee, might well be termed a much larger *Sandown Brilliance*, for it possesses in an increased degree the glorious colour and substance of that fine variety. Shewn by Mr. G. Carpenter.

Brasso-Cattleya Alma.—A strikingly beautiful hybrid more nearly approximating the *Brassovola* than a *Cattleya*. It is a very large flower and the broad sepals and petals are the colour of very old ivory, while the beautifully fringed lip is a delicate pale rose pink, freely veined with golden yellow. Award of merit to Messrs. Charlesworth and Co.

Brasso-Cattleya Wm. Pitt.—The *Cattleya* parentage is very evident in the rich mauve sepals and petals which colour is continued in the large, fringed lip where it is relieved by yellow flushing in the throat, making it a very showy flower. Award of merit to Mr. W. Pitt.

Cattleya Our Prince.—A wonderfully beautiful and uncommon flower of rose and gold colours. The broad sepals and petals are glistening golden yellow, while the slightly constricted lip is old rose colour, very freely lined with deep golden yellow. Award of merit to Messrs. Flory and Black.

Cypripedium Gwen Dixon.—A very dainty warm greenhouse Lady's Slipper Orchid of *C. Spicerianum* type. The dorsal sepal is pure white while the remainder of the flower is of delicate greenish-yellow colour. Award of merit to Mr. L. Dixon.

Cypripedium Linda.—This is a larger and more rounded bloom of the Dreadnought or Bull Dog type and though a trifle smaller than these is still a large flower, but carries the characteristic somewhat squat habit and rounded shape. It is of greenish-yellow colour with pure white on the

upper half of the large dorsal sepal. Award of merit to Messrs. Cowans, Limited.

NEW FRUIT.

Apple Joy Bells.—Although its origin is unknown the general appearance of this seedling Apple suggests Bismarck and Emperor Alexander, though it is of superior quality to either. It is a juicy, sweet, aromatic November Apple, but larger than is generally preferred for the table. In shape it is much like Bismarck and very brightly coloured on quite three parts of its surface, the remainder is a pleasant yellow. Award of merit to Mr. Will Taylor.

THE CHRYSANTHEMUM SOCIETY'S SHOW

NEVER before have such magnificent exhibition Chrysanthemums been seen as at the R.H.S. Hall, Vincent Square, on November 16 and 17, when the National Chrysanthemum Society held its annual show. Not only was there an appreciable increase in the size of the blooms, but the quality was decidedly the highest ever seen in this or probably any other country. The season seems to have been particularly favourable to the production of beautiful floral colouring, and in practically all the many blooms in the hall the clarity and depth of colour were most noteworthy.

While it is a tribute to the great skill of the chief cultivators and, to a certain extent, the raisers of Chrysanthemums, this increase in size is not altogether an unmixed blessing. As ever, it brings a rather serious problem in its train. Already the exhibition board has proved too small fully to display the manifold charms of these gargantuan blooms, and on the present occasion

it was still more inadequate. It might well be said that the remedy is to dispense with boards altogether and to display the blooms more naturally and gracefully in vases. This would be the counsel of perfection, but there are decided objections to its adoption for all the classes. It is a difficult matter to transport sufficient exhibition blooms on long stems to set up a collection in the Holmes' Memorial Class, for instance. We are fully aware that this was done in the William Wells' Memorial Class, which requires the same number of similar blooms, but the greater number of exhibits in the former class indicates the truth of our statement, and it applies most to those exhibitors who live some distance away.

The increased size of blooms is not the only problem before the Society. Its increasing success

GOLDEN SINGLE CHRYSANTHEMUM ORIOLE.

requires even more serious consideration. Last November, and again this year, it was abundantly borne upon the executive that in every way the Vincent Square hall is too small.

Great as is the improvement in the large Japanese blooms, which many thought years ago had reached their apogee, it was the single-flowered varieties that shewed the most marked improvement. This elegant and useful class is as yet only in its infancy, and we confidently anticipate that the day is not far distant when we shall see quite distinct as well as improved types.

The greatest effect was seen in the large-flowered singles, and the George Mouro Cup was won by Mr. H. Woolman with beautiful examples of such sorts as Edith Dimond, Mars, Esme Waters, Sandown Radiance, Molly Godfrey and Reg. Godfrey.

The trade growers supported the show in very generous fashion. Mr. H. J. Jones freshened his enormous group of the previous Tuesday to such good purpose that he was awarded a Special Large Gold Medal and the compliments of the Committee for making the most comprehensive and representative collection ever seen at the Society's shows, and also the Clay Gold Medal for the best trade group in the show. To date Mr. Jones has won ten gold medals in fourteen weeks, which is a record not easily to be broken. It was quite a stupendous exhibit, and made a feast of floral colour that will be long remembered by all who saw it. At the back there were tall stands chiefly filled with large exhibition blooms of high quality. Below were ranged large baskets of decorative sized Japanese and single varieties, with occasional baskets of Pompons and Anemone-flowered varieties.

On the opposite side of the hall Messrs. W. Wells and Co. had a beautiful collection which won a gold medal. Many of the exhibition

MR. H. J. JONES'S MAGNIFICENT EXHIBIT

Japanese varieties would have done credit to a first prize exhibit, and such as Majestic, Louisa Pockett, Mrs. G. Drabble, Mrs. George Monro, jun. and Wm. Rigby were shown in quantity.

Another gold medal collection was contributed by Messrs. Keith Luxford and Co., and in addition to many exhibition Japanese, Decorative and Single varieties, it included a fascinating vase of such dainty little Pompons as Golden West, Snowdrop, Mary Pickford and Baby Doll. The vases of the graceful Anemone-flowered varieties also attracted attention. Thora, a rosy mauve which has a straw-coloured centre, was particularly admired.

Silver-gilt medals were awarded to Mr. H. Woolman and Mr. W. Yandall for graceful collections. In the latter the baskets of Bronze Molly, Josephine Bernier, Mavis and Mr. W. Smith were very successful; while Mr. Woolman had well grown examples of the Japanese varieties Ida, Miss A. E. Roope and Mrs. J. T. Henry. Collections were also shown by Messrs. J. W. Cole and Son, Messrs. W. J. Godfrey and Son and Baron Schröder.

NEW CHRYSANTHEMUMS.

The Floral Committee of the N.C.S. found forty-eight novelties awaiting judgment. Nearly all of them were of merit and the following were selected for award.

Absolute.—In the opinion of several specialists this is the finest single in cultivation. It is of medium size, perfect form and most delightful shade of amber with a suggestion of orange, and a golden zone. First class certificate to the Bridgewater Nurseries Company.

Crimson Perfection.—A very handsome Japanese variety of rich velvety crimson colour and useful decorative size. First class certificate to Mr. C. J. Henderson.

Floria.—A valuable pink single Chrysanthemum of medium size and good form. There is a small white zone to the flowers. First class certificate to the Bridgewater Nurseries Company.

Hilda Shoemith.—A well formed single with broad, blunt, silvery pink florets slightly drooping at the tips. First class certificate to Mr. Jas. Shoemith.

Mrs. R. Harris.—A bright yellow single Chrysanthemum of round form. The broad florets recurve slightly at the tips. First class certificate to Mr. Walter Jinks.

Nero.—A medium sized market Japanese variety of flaming crimson colour. The broad, slightly drooping florets give the blooms a graceful appearance. First class certificate to Mr. H. Shoemith.

November Cheer.—This is a rose pink market Japanese variety of distinct cup-shaped habit. It appears to be a bloom that will travel exceedingly well. First class certificate to Messrs. W. Wells and Co.

Poulton's Climax.—An exhibition Japanese variety of large size and very graceful habit. The long white curled florets droop and, since there are plenty of them, give an elegant appearance. First class certificate to Mr. H. Poulton.

Radiant. This is the gloriously beautiful single variety that failed to receive recognition at the previous R.H.S. meeting. First class certificate to Mr. G. Carpenter.

Sunset.—This is a very attractive single-flowered Chrysanthemum of Mensa size and bright amber colouring and though not so regular in shape as Mensa, it is an elegant flower. First class certificate to the Bridgewater Nurseries Company.

Wellington Wack. Although the florets are narrow and stiff, this is a graceful market Japanese variety of uncommon pale primrose colouring. First class certificate to Mr. E. Jones.

THE PLANNING OF A GARDEN ORCHARD

SITUATION.—First we will discuss the situation, although I am afraid we are not always able to choose for ourselves. It should afford, if possible, some protection from the north and east and also from the local prevailing winds. Damp and low-lying situations should be avoided, as should dry and really sandy soils. If natural protection is lacking, hedges and windbreaks should be planted, and if fruit of large size or of a delicate constitution is to be grown, then a wall would be a great help and even a necessity in some cases. Wooden fences are not to be recommended, as they are not profitable and harbour a lot of insect pests, especially if they are of the rustic type with the bark left on. Trees on a slope facing south-east or south receive the full force of the sun's direct rays in the early morning and if a frost should occur the rapid thawing will often destroy some of the blossoms. Therefore it is not wise to plant an orchard on a slope of this description.

Preparation.—The type of soil must be considered, and I would say at the beginning that the most generally suitable is a medium loam of moderate depth resting on a well drained subsoil. If it were grass and there were no immediate hurry, then the best plan would be to dig up the grass in August or September and let it die on the land, choosing a spell of very dry and hot weather if possible. If wet prevailed, then the grass would in all probability take root and it would have to be dug all over again. If only quite a small area was being planted and if time was pressing, then the sods could be carted off and heaped to rot down. This would waste no time and the thorough digging could then be commenced straight away. To kill any pests, such as wire-worms, which infest grass roots, a dressing of some good soil insecticide would be advisable. Gasonite is one which is reliable, and should be spread on the top after the shallow digging at the rate of about 50lb. to 1 rood. When the grass has died down then the thorough digging must be commenced. Good stable manure should be applied at the rate of five tons to the rood if the soil is in poor condition. However, if the land underneath the trees is to be kept open and unplanted, then manuring would be inadvisable for the present. If Strawberries, vegetable crops or flowers are to be grown, then apply manure as above. The land should preferably be trenched and the subsoil should be broken to a spade's depth. Care should be taken, however, not to bring any sour subsoil up to the surface. It is very necessary when planting a new orchard to remember that the soil should be in excellent heart, be well drained, and be kept open with fibrous matter, such as long straw manure, dead leaves or ashes. These are essential points for the best growth and heaviest yields.

Windbreaks.—Anyone who has grown fruit on a rather exposed situation will know the damage caused by an unexpected high wind, especially if the trees are standards. It certainly pays to protect such an exposed garden with a windbreak of some description. Poplar, Hawthorn and Privet are very useful and generally planted, but why not grow a profitable wind screen? Plums, such as Monarch or Czar, I have seen planted thickly enough to afford a considerable amount of shelter, and such tall-growing Pears as Catillac and Fertility can be used and will be found serviceable and profitable. Pear and Apple trees for this purpose are best bought as "feathered" trees (i.e., unpruned when one year old), planted about 12ft. apart, and allowed to grow up naturally and without training them to any special shape. Plums and Damsons should be planted closer

than this, the usual distance being 8ft. to 10ft. If a hedge to prevent pilfering has to be formed, then I should suggest planting Hawthorn and interplanting with Czar Plums 12ft. apart. Here you have a close and profitable boundary and windbreak combined. No wind screen should be planted on the south side, because it would hide the sun from the crops growing within a distance of 10ft., and poor results would be obtained therefrom. Although these breaks seem unnecessary to some gardeners, I am confident that an increased yield of sound fruit would result from their use.

Marking Out.—When the ground is ready the exact position of each tree should be marked with a stake. These positions are easily marked out by means of an ordinary chain with pieces of tape tied on to it at distances apart equal to the correct distances at which your trees are to be planted. Get your base line first and by means of a home-made square or a surveyor's instrument the various positions can be marked off, drawing the chain along as you want it. Any stakes that are out of alignment when finished can easily be corrected by sighting along each row.

Planting.—Now as to the actual planting. This may be done from the middle of October to March, but the sooner they are planted after they have dropped their leaves the better. The ground will be more easily worked and the trees will be able to form new root fibres before winter sets in. The method of planting is most important, because growth is checked on transplanting and everything must be done to give them a good start in their new quarters. The first important point is the careful treatment of the trees, especially the roots when actually out of the ground. They must not be exposed to frost or drying winds, and if on arrival, the roots are found to be shrivelled up, plunge them into a tub of water for twenty-four hours. Also any damaged or thick tap roots should be cut off with a sharp knife, taking care to make the cut from the centre of the tree and with its face downwards. Thus new lateral roots will be encouraged.

Each hole should be dug out, leaving liberal space for the roots of the trees without cramping. For trees worked on the dwarfing stock the depth of planting should be so as just to cover the junction of the scion and stock, otherwise an unsightly protuberance will result, and when it attains the size of a football it will not reflect much credit on its owner! Trees on the free-growing stock should be planted at the same depth as they were in the nursery rows, which can be seen by the soil mark on the stem. When the hole has been dug, then drive in your stake. This is much better than putting it in after the tree has been planted and damaging the roots and, incidentally, damaging the tree by a misjudged blow.

Carefully place the tree in the hole and spread out the roots flatly and evenly distributed. Now, when the alignment is correct, shovel in a *little* of the best soil and stamp down with your heel. Then a little more soil and tread firm again, and keep on in small quantities until the hole is filled. This is the secret of good planting, and ensures a good start for the tree in the following spring. It is useless to fill in the hole all at once and tread down the top. A drying of several of the roots will result and in some cases the ultimate death of the tree. Leave the earth round the tree slightly higher than the surrounding ground to allow for gradual consolidation, or otherwise a hollow will result which will make a harmful pit for water. Also leave the ground loose and not just as it is after trampling down. SEE-JEE.

CORRESPONDENCE

"BEAUTIFUL FLOWERS AND HOW TO GROW THEM."

IN reference to the review of this book in your issue dated the 11th inst., suffice it to say that it is thirteen years since it passed through the hands of either my brother, Walter P. Wright or myself.—HORACE J. WRIGHT.

AN EARLY NARCISSUS.

I BELIEVE the stock of that fine Narcissus Henrietta is in the hands of Messrs. Cartwright and Goodwin of Kidderminster, but it was raised by Mr. W. F. M. Copeland. It is one of the rather small class of all yellow *Incomparabilis*. Its perianth is not quite "up to the knocker" from a florist's standpoint, but it has the making of a fine garden plant, being large, tall, robust, a fast increaser, very floriferous and extremely early. This extract from a letter which I recently received from "C. and G." in answer to one from me enquiring how early? speaks for itself: "In 1921 it was the first variety to flower. We have not got the exact date, but it was completely over long before the R.H.S. Daffodil Show, while this year it was the only bloom out for that show that had not been forced on. On March 18, 1921, Henrietta was past its best. We have this record." These early varieties help to prolong the Daffodil season out of doors at one end, while such a one as Steadfast does the same thing at the other. Then come the Poets; and then, after *recurvus* and the old double white, the end. I am very glad there is an end. Not even Roses and Carnations are loved any the more for being always with us.—JOSEPH JACOB.

THE TWELVE BEST SHRUBS.

THE interest in the selection of the twelve best flowering shrubs seems to be increasing week by week, and no wonder, as no more fascinating subject could have been introduced to readers of THE GARDEN. As was to be expected, the various lists show widely divergent choices, because some beautiful shrubs which succeed well in favoured localities are anything but satisfactory in others. Individual taste is also a very important factor in choosing flowers of any sort, and the great variety both in habit of growth and form and colour of flower among shrubs allows an extra wide latitude in this instance. It is a pity that Roses and Rhododendrons were permitted to enter the arena, not because they are unworthy, but because of their sterling worth, as we think they

are each worthy to form a class by themselves and could without difficulty provide a choice dozen in either group. Another feature which should be taken into consideration, is the hardiness of the shrubs, as some were mentioned in several of the lists which it would be foolishness to attempt to grow in Scotland, except in the highly favoured localities on the west coast. In making my selection I have kept these points in view and also have purposely chosen shrubs of moderate growth, which can be grown in even the smallest garden, consequently some choice large-growing things

ALL YELLOW, NARCISSUS HENRIETTA.

such as Laburnums, Lilacs, etc., have necessarily been omitted. The list also includes such species as will provide bloom for as long a period as possible. My choice is as follows:—*Forsythia suspensa*, *Daphne Mezereum*, *Andromeda floribunda*, *Spiraea arifolia*, *Ribes sanguinea*, *Escallonia langleyensis*, *Philadelphus Lemoinei*, *Berberis stenophylla*, *Olearia Haastii*, *Weigela Eva Rathke*, *Ceanothus Gloire de Versailles*, *Buddleia variabilis Veitchiana*.—ALBYN.

THE COLOUR OF ROSA MOYESII.

THE note from Mr. A. B. Bruce on "the colour of *Rosa Moyesii*," in your issue of November 11, filled me with surprise. The writer states that "'brownish-red' and 'blood-red' are misdescriptions suggesting the spurious variety mentioned." He also states that he has "seen at shows a plant with all the characters of *Moyesii* except that the colour of the flower was a *hideous* combination

of brown, red and yellow!" I have seen *R. Moyesii* both at the Oxford Botanic Garden and the Botanic Garden, Cambridge, as well as at the shows, and this Rose is quite accurately described as brownish-red (or even blood-red, if the blood has become dry), but the great characteristic of *Moyesii* is that there is *not a trace of yellow* shading on either stamens or petals and certainly no trace of old rose pink—a rich maroon might convey a fair idea of the colour or a tawny deep rich Indian red or even tawny port.—H. H. WARNER.

ERIGERON MUCRONATUS.

"CAMBRICA" makes a curious mistake in describing this little Daisy flower (see page 560). To begin with, this is its proper name, though I believe a certain number of nurseries sent it out as *Vittadinia australis*, endemic to New Zealand, which I have raised from seed and is utterly different from *E. mucronatus*, which is a native of Mexico (see Nicholson). Secondly, the colour of the opening of the flowers is exactly reversed—they *open* white, "tip-tinted," certainly, with pink, like our common Daisy, but die off to almost a crimson, as you will see from the flowers enclosed (in every stage). It is truly an almost everlasting flowerer and is best and neatest if clipped over closely in spring, just before making its new growth. An excellent plant for an edging among stones.—WESTERN WIGHT.

[*Erigeron mucronatus* appears to be identical with *Vittadinia triloba* (not *V. australis*), but as sent out from nurseries the two plants are too often identical. The flowers sent were nothing but seed heads on arrival.—ED.]

BULBS IN OUT-OF-THE-WAY CORNERS.

THERE are nooks and corners in many gardens, sometimes at the foot of walls or beneath overhanging trees, where the advent of spring brings no change and fails to mark with her light fingers of beauty "the days and weeks with bud and blossom"; where, indeed, little attempt has ever been made to brighten them. Not infrequently it is because some of these corners *are* out of the way and do not appear within sight of windows of the home that they are neglected. One such garden with which we are acquainted has come under the transforming influence of lowly treasures. Some of them, like the Winter Aconites (*Eranthis hyemalis*) shew their golden blossoms while the year is young, followed hard on by Snowdrops and bright blue *Scilla sibirica* and *Chionodoxa sardensis*. A little colony of that gem among Anemones, *nemorosa* var. *Robinsoniana*, never fails with its sheeny sky blue flowers that open wide their petals in the spring sunshine. If planted near to, or in conjunction with, groups of Narcissi, the effect is most marked. Time and again one notices bare spaces in the vicinity of shrubs that—if a summer use cannot be made of them—may at least by planting small bulbs be rendered attractive in spring. Besides those mentioned, Muscaris, Crocuses and *Fritillaria Meleagris* are serviceable. None of these plants is fastidious. They involve little trouble once planting has been done: there is no necessity to lift them very often, and they can well be left to colonise without much sign of deterioration. In a corner in our own garden, nestling up to a wall, that early Crocus Cloth of Gold has now for many years shewn its bright yellow face practically simultaneously with Scillas, and at the time the bulbs have been left to themselves. It is these out-of-the-way, little regarded positions in a garden that can be made real beauty spots in the morning of the year if only we seek to make them so by planting what cannot fail to bring beauty and pleasure in their train—flowers that blossom early.—L. W.

PLANTING THE ROSE GARDEN

THE Rose is said to be the Queen of Flowers. She has certainly an imperious way with her which lends some colour to her sovereignty! The best site in the garden is, in too many cases, hardly good enough for her. So was it in our case. We picked the best site we could, however, remembering that poor soil may be improved but that light and air are more difficult to control.

I should, perhaps, make it clear that we were new-comers to an old garden when we decided that a Rose garden, however small, must be added to the existing garden scheme. The site ultimately decided upon was sheltered from the north by a screen of conifers, interplanted effectively enough with Lombardy Poplars and Silver Birches. This screen would have been better a little further off, but it provides shelter from biting winds and also adds greatly to the privacy of the garden, which, but for it, would be overlooked.

On east, south and west there was nothing of sufficient size to obscure light or to cause draughts; nothing, at all events, of such value that it could not be sacrificed. The soil itself was as poor as could be; part of it, however, was under turf, which was incorporated face downwards all over the garden as trenching progressed. The larger part, however, had once been planted thinly with shrubs, some never first class, some quite good kinds, but all quite overgrown and useless. The ground was simply alive with twitch. From late spring until early autumn unremitting war was waged on this and other weeds, but the work of destruction was complete, for the following season (1922) none of this insidious grass showed up and even annual weeds were scarcer here than elsewhere in the garden. I believe that the great thing in dealing with twitch, and with other weeds with underground "wires" for that matter, is to preserve the root mats as entire as possible. Once get it broken up into bits an inch or two long it is almost beyond the wit of man to eradicate it in a single season.

No doubt this very necessary fallowing helped to enrich the ground, but a dressing of cow-manure was added to the lower levels with the view of improving its texture. There was some doubt about the fertilising value of the only cow-dung procurable, however, and it was accordingly supplemented with really good stable manure. The ground was trenched two good spits deep and the subsoil broken below. The manure was incorporated into the bottom spit and the chopped up turf between the top and bottom spits. Finely ground bones, not bone-meal, were also dusted between the spits as the work proceeded. The land, though poor, seemed sweet, but its lime content on such a soil would be small, so, without troubling to test it, a dressing of ground limestone at the rate of about $\frac{1}{2}$ lb. to the square yard was spread on the surface and afterwards lightly forked in. A dressing twice as heavy is quite usual, but, personally, I think it is more satisfactory and less wasteful, at any rate on light land, to apply smaller dressings at more frequent intervals.

All this work was completed early in September, and by the beginning of November the ground, having been well firmed when trenching took place, was ready for the trees. The paths were all marked out and levelling pegs put in, but the turf was not laid until after the Rose trees were planted. The object of this was to prevent the beds being trodden off the newly laid turf before it had a chance to get established. I have since come to the conclusion, however, that where turf is to be laid it would be better to get this done in early autumn and leave it to establish itself,

allowing the usual pins, or jins, of "overhang" to permit of trimming and leaving this trimming until planting is finished. There was rather a lot of re-levelling to do before the turf could be laid and though in the end an entirely satisfactory result was obtained, I am convinced it was not economical.

The Roses were planted in the way so often described in *THE GARDEN*. A hole amply large enough was made and the roots spread out somewhat. No attempt, however, was made to make the fibrous roots run all ways from the main tap-root. They were encouraged to lie as nearly as possible in the same relative direction as they had done when growing in the nursery. The ground was made quite solid as the work proceeded, but the surface was forked up and left moderately rough for the winter. In spring Mauve Queen Violas were planted as a double edging round the beds. These were a great success, and this season I purpose planting them in the centres of the beds also to form a continuous undergrowth. Except for a fortnight or so about July when they are cut over they produce a display of beautiful colour all summer through. They are particularly valuable when Rose blossom is rather scarce.

For my own part I think an elaborate Rose garden with complicated beds a sad mistake. The appearance of grass is preferable to that of paving in a Rose garden. In our own case we introduced paving down the centres of the main paths to give comfortable access in early morning when the dew is on the sward or after rain and also to save the damage to the turf which is likely to be caused by the gardener's barrow.

For the twenty beds in the garden the following varieties were employed, one sort in each bed: General McArthur, rich crimson, very fragrant; Lady Hillingdon, golden buff, tea-scented; Mrs. Herbert Stevens, white; Ophelia, flesh colour; Mme. A. Chatenay, pink; Prince de Bulgarie, soft pink tinted yellow; Pharisæer, silvery rose; Mrs. A. R. Waddell, coppery tones; Mrs. Wemyss Quin, bright yellow; Château de Clos Vougeot, black-crimson; Mrs. George Shawyer, pale rose; George C. Waud, red; Molly Sharman Crawford, ivory white; Mme. Segond-Weber, salmon rose; Lady Pirrie, coppery salmon; Joseph Hill, salmon pink; Mme. Ravary, soft yellow; La Tosca, flesh colour; Jonkheer J. L. Moek, deep carmine rose; and Isobel, orange scarlet. One keeps learning by experience, and I have found Joseph Hill and La Tosca too tall compared with the others and Mme. Ravary too dwarf. An abundance of soft colours is very necessary to bring into harmony some of the daring shades now in favour.

S. A. N.

PARIS INTERNATIONAL AUTUMN EXHIBITION

THIS Exhibition opened on October 27 and closed on November 5th. It was held in the Palmarium and adjoining greenhouses in the Jardin d'Acclimatation, Paris. Unfortunately the night previous to the opening a sudden frost took place, with the result that the Begonias and many of the Chrysanthemums were greatly disfigured.

The Committee of Patronage was composed of many eminent names in horticulture in allied and neutral countries and on the jury were members from Belgium, Spain, Switzerland, Poland, Italy and England, besides France. The Show was very tastefully arranged, a piece of artificial water,

crossed by a rustic bridge, formed an attractive centre, around which were grouped several of the most important exhibits. At the far end of the Palmarium, leading to the adjoining hall, on each side of the steps were two large masses of rock which also helped to give an artistic effect to the Show.

On one side of the Palmarium was a long greenhouse or annexe filled with the fruit exhibits and on the opposite side was a series of small greenhouses, each containing some special class of exhibits, such as Orchids, Japanese dwarf trees, etc. In the grounds close by was another large greenhouse devoted to the vegetable classes, a grand display by various exhibitors of every conceivable vegetable in season. Chrysanthemums, of course, occupied the principal place and the Grand Prix d'Honneur was awarded to Messrs. Vilmorin Andrieux et Cie for an enormous display of trained and specimen plants arranged in several sections. Most of the plants were of decorative value only, being covered with medium-sized blooms and were principally French varieties. M. G. Truffaut put up a remarkable display, consisting of five huge columns of blooms, one variety in each, and a series of circular groups, on a soft green moss ground, of large exhibition blooms. His finest flowers were Undaunted, Captain Fox, Mrs. G. Drabble, Majestic, Mrs. R. C. Pulling, Paul Oudot, Miss Edith Cavell and other well known English varieties. Close by was the very meritorious group staged by M. Paul Féron. On a square turf lawn, decorated with autumn foliage, were some large vases with one in the centre standing on a blue porcelain pedestal. They were filled with colossal blooms of Mrs. R. C. Pulling, Edith Cavell, Undaunted, Daily Mail, Captain Fox, etc., also a few singles in front.

M. Leloup-Grimoux staged a most important group in two parts, divided by the path leading to the main body of the Show. A large number of well known English varieties, and some French made up this exhibitor's very fine display. The Maison Féron staged singles, and other prominent exhibitors in Chrysanthemum classes were Messrs. Oudot, Liveque et fils, Lochot, Mme. Martin (new seedling), Souchet-Laurent, R. Viallette (a nice collection of Japs), Ragot, Laveau and G. Morin.

The Floral Committee awarded a large number of certificates for new Chrysanthemums, but these are hardly likely to interest the general reader.

M. Aug. Nonin showed Roses and Camellias. In the former Joseph Guy, Mme. Abel Chatenay, Mme. Butterfly, Lady Hillingdon, Orleans Rose, etc., were presented in nice form. Messrs. Leveque and Honoré Difresne also staged Roses. Carnations were not plentiful, but some interesting lots came from Messrs. Leveque, Davy and Vacherot. Messrs. Cayeux and Leclere put up an attractive mixed group of Dahlias, Chrysanthemums and Michaelmas Daisies. Some good exhibits, as usual, came from the well known tuberous Begonia specialists, Messrs. Vallerand and Billard. Cyclamen artistically arranged along the banks of the artificial water came from M. Ragot. Mme. Aubert-Maille had a grand lot of the same, with other plants. Floral art was well represented by the famous Paris house of Lachaume, and also Ed. Debrie, whose artistic displays were much admired. M. G. Weiss staged Japanese dwarf trees and in the little side greenhouses we noted the exhibits of fruit by M. Lepère, M. Lambert, Pestel and others.

A large side greenhouse contained the leading fruit classes, some of them nearly roof, long, on tables, the chief exhibitor being the well known firm of M. M. Nombrot-Bruneau, Croux et fils and Moser et fils, Apples and Pears being in the majority. Vegetables were shown in a separate house in great variety by Messrs. Vilmorin Andrieux et Cie, M. George Truffaut and M. Davy.

HOME-BREWED WINES AND UNFERMENTED BEVERAGES for all seasons of the year. By ANNE AMATEUR. A helpful booklet containing also recipes for invalid drinks, and published at 9d., post free 11d., at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, W.C.2

DAINTY DISHES from Odds and Ends, by J. J. WILLIAMS. An invaluable booklet for the perplexed housewife is to be obtained from the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, W.C.2; 9d. or with postage 11d.

BUILD ON A GOOD FOUNDATION.

In planting a garden or an orchard, whether large or small, for pleasure or for profit, it is important to lay a good foundation.

This means thorough preparation of the ground, careful planting and, above all, healthy, reliable, well-rooted trees, of good constitution, of the right sorts on the right stocks.

Inferior fruit cannot find a profitable market. Good fruit can command one.

We specialise in fruit trees for Market Growers or Amateurs, and shall be pleased to give intending planters the benefit of over 40 years' experience in fruit growing.

Roses, Shrubs, Perennials and Alpines are equally well grown.

THE ARRANGEMENT OF FLOWERING SHRUBS

PRESENT-DAY tendencies in gardening are all towards making greater use of flowering and fruiting shrubs with trees small enough to be grouped successfully with them. This is understandable enough for many shrubs are extraordinarily beautiful when in blossom, others are exceedingly attractive in autumn, while others, again, brighten the landscape in winter-time when herbaceous borders present only a stubble—and an unattractive greyish stubble at that. Though their beauty be amply sufficient to justify and account for the increasing popularity of shrubs, it is more than doubtful whether it furnishes the only or, indeed, the principal reason for their rapid progression in public favour. The fact is that the well arranged shrubbery, representing, as it does, the maximum of beauty with a minimum of labour, exactly meets the need of a period of world-wide impoverishment. A series of articles upon different families of shrubs and trees has, doubtless, proved helpful to those desirous of selecting the species and varieties best suited to their purpose. To-day it may be well to consider how to dispose our material—living material be it noted—to produce adequate effects at different seasons.

The best soil for the generality of shrubs is unquestionably a light, practically lime-free sandy loam. It can, with very little trouble or expense, be made to suit all classes. Fairly well rotted leaf-mould, spent hot-bed manure and turf loam will fit it for Rhododendrons and other American plants and the addition of mortar rubble or ground limestone will render it suitable for trees and shrubs needing lime.

Fig. 1 on page 600 shows an arrangement of shrubs to a curving entrance drive. Such a drive is often necessary owing to a discrepancy between the

level of the roadway and that of the house. The opening shown on the right indicates a connexion to some of the more open parts of the pleasure grounds, perhaps to a more extensive shrub garden. This opening is suggested as a turf sweep, but it might be desirable to take a dry paved path, a gravelled walk, or even a subsidiary cartway through such a gap. Actual planting in such cases must largely depend upon individual tastes and preferences, but the scheme shown will suggest suitable proportioning for the different groups. It will be noted that Holly, the practically smooth-foliaged laurel-leaved variety to wit, is suggested to give solid background on occasion. If a fair amount of land may be devoted to such backing, Common Spruce (*Picea excelsa*) or, preferably, the Oriental Spruce (*P. orientalis*) may be utilised instead. The tree commonly employed, *Cupressus Lawsoniana*, is less suitable, being dull and commonplace of foliage, yet in some of its better forms it will serve. Trees which ultimately attain any height should not be used anywhere in the immediate vicinity of the house. One might think it unnecessary to mention this, but

experience shews that such unsuitable planting is an almost everyday occurrence.

To turn to the actual shrub planting suggested, objection may be taken to the use of Rock Roses. The fleeting character of their blossoms may be pointed out as well as their want of hardiness in many inland counties. The short-lived character of their individual flowers granted, however, it must be pointed out that the bushes remain effective over a very considerable period. The second objection is more serious. The only species absolutely hardy in some inland counties is *Cistus lanifolius*, though *C. cypricus* (usually sold as *ladaniferus*) and *purpureus* are moderately so. Their places in the plan might be occupied by *Cydonia Maulei* or Japanese Maples and *Cytisus nigricans Carlieri* respectively. Where no species is mentioned (*e.g.*, Barberries, Brooms) it is intended to plant a variety, but care must be taken only to associate together sorts which suit both as regards habit and colouring. Azaleas are suggested to be used fairly freely. Mollis seedlings are best for such a purpose, and may be had in a wonderful range of colouring from flame, through

salmon pinks, to soft yellow. Not only are they gorgeous when in blossom, but they are among the best and most certain shrubs for autumn foliage colour. The planting as shown might be improved by including, here and there, odd plants of *Forsythia* and *Hamamelis mollis* to give colour in the dark days. *Escallonia macrantha* is an admirable and, on well drained ground, a hardy shrub which has beautiful foliage and is almost always in flower.

In Fig. 2 suitable planting for a comparatively short straight drive is indicated. It has often been stated that shrubs are less effective in straight-edged borders than in those of curving

THE RHODODENDRON WALK AT ALDENHAM.

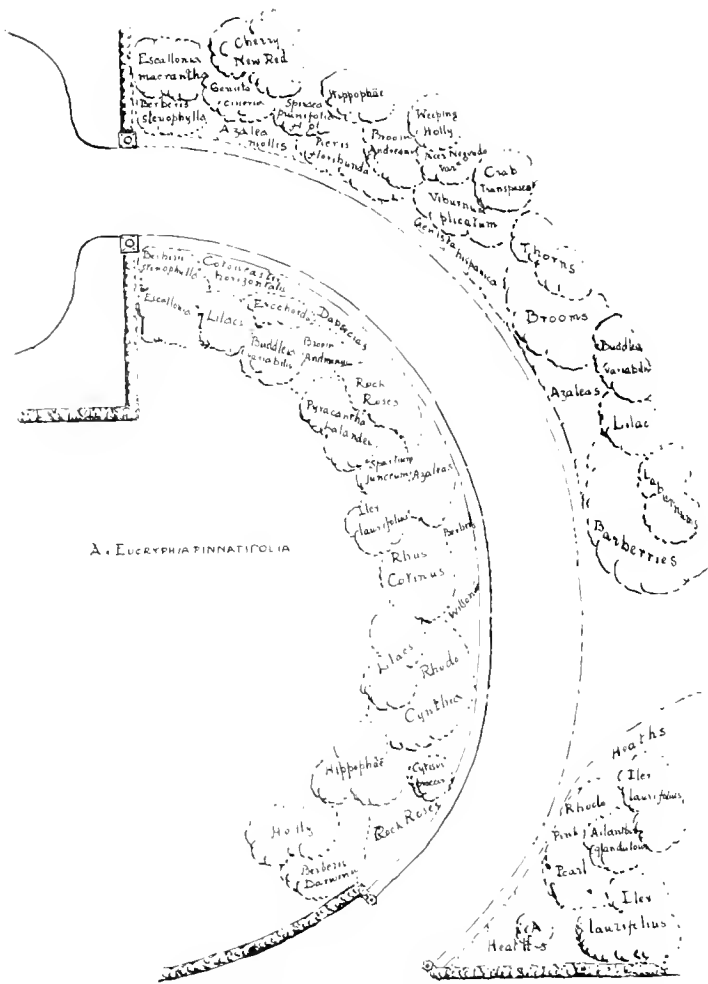

FIG. 1.—SHRUBBERY PLANTING TO A CURVED DRIVE.

outline. That there is some truth in the contention few will deny; none the less, given sufficient spacing properly to see the borders, shrubs may be used in such borders with admirable effect. There are strips of turf on either hand, which should, if possible, slope gently up to the shrubs. The Thorns suggested might be *Crataegus Oxycantha* var. *Single Scarlet*, which, if less lasting than Paul's Double Crimson, is more beautiful and has the additional substantial merit of fruiting abundantly in autumn. One or other of the large-fruited American species might be substituted if desired. The *Spiraeas* suggested would be *S. Lindleyana* and either *S. arguta* or *S. prunifolia* fl. pl., with *S. Bumalda* Anthony Waterer (rosy crimson) in front. The *Skimmias* have very desirable evergreen foliage, and are admirable for lasting berry effects. It is necessary to include at least one male plant in each group.

The *Azaleas* will again be mollis hybrids in

and, when in flower, the sheet of gold is unrivalled. It sometimes gets cut with frost pretty severely inland, but it is very seldom that it fails to throw up again from the centre of the plant. The most attractive *Kalmia* is, unquestionably, the Mountain Laurel, *K. latifolia*, but *KK. angustifolia* and *glauca* are interesting and useful for the front of the group. The American Spindle Tree, *Euonymus latifolius*, is a really handsome fruiting shrub, and also gives valuable autumn colour in favourable seasons. Though all *Euonymuses* bear fruits more or less, there are distinctly male and

female forms, and one of the former should be included in each group.

If the group of *Lilacs* is confined to one variety, probably *Charles X* would be as satisfactory as any, but a plant of the white *Marie Legraye* might be included without looking odd. *Berberis Thunbergii* is quietly beautiful when its pinkish buff flowers expand, but is chiefly noteworthy as being the most gorgeous of many brilliant shrubs when in autumn dress. To match its salmon and copper tints in any other autumn foliage one has to turn to extra well coloured current season's growths of the self-clinging Virginia Creeper, *Vitis inconstans* (syn. *Ampelopsis Veitchii*). The other fairly dwarf *Berberis* shewn might include *B. Wilsonae* (or *B. subcaulilata*) in front and *B. polyantha* behind, both admirable for their fruits, or some of the *Mahonia*

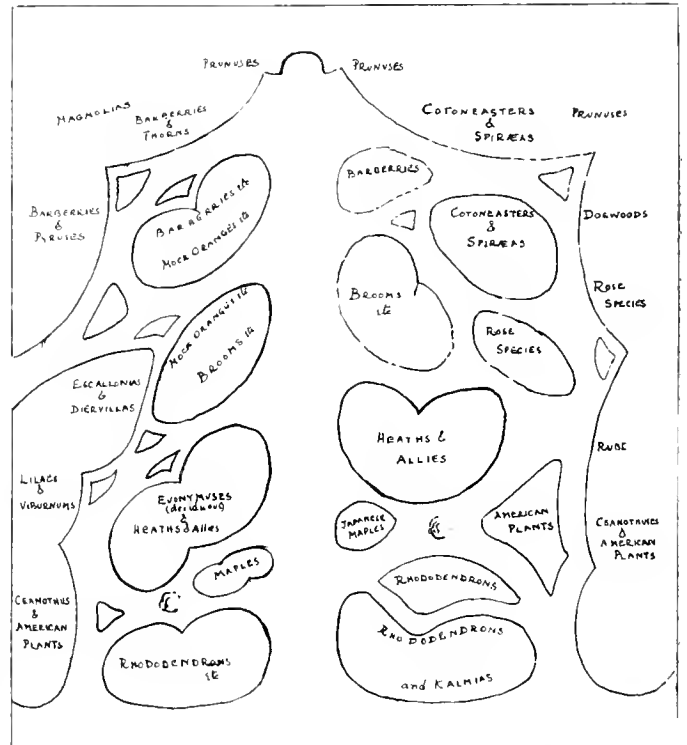

FIG. 3.—ILLUSTRATES PLANTING "BY FAMILIES."

Much of the distaste which is felt for shrub gardens in some quarters is due to spotty "higgledy-piggledy" planting.

group might be substituted. They are attractive in flower, foliage and fruits, though these last are less showy in their violet dress than the coral and crimson berries of the purely fruiting species.

The most useful of the variabilis *Buddleias* is probably the variety *magnifica*. *Philadelphus grandiflorus* is one of the best of the *Mock Oranges*.

It flowers when the forms of *coronarius* are over. Its total lack of scent may, or may not, be considered a disadvantage. It is rather surprising that *Veronica salicifolia* has not been mentioned in the correspondence ament the "twelve best shrubs." When seen under favourable conditions it always draws favourable comment, and it is certainly entitled to be considered the handsomest of even "theoretically" hardy shrubby *Speedwells*. It is probably harder than *Laurel*. The deepest possible red form of *Ribes sanguineum* should be procured. Such forms are often listed under fancy names.

The hybrid *Escallonia*, *E. langleyensis*, a cross between the white and deciduous

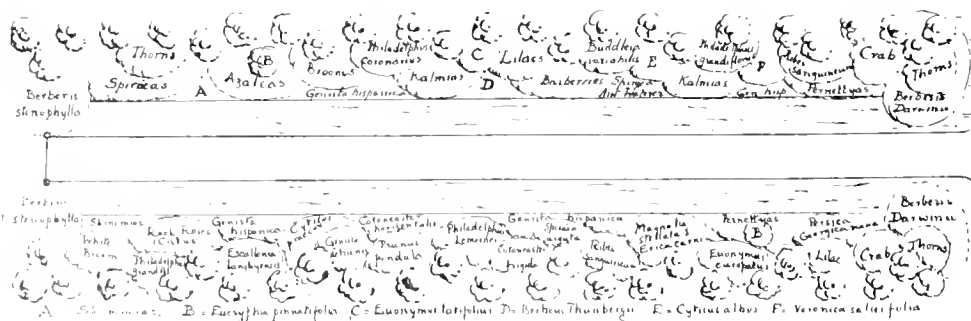

FIG. 2.—PLANTING AND LAY-OUT FOR A STRAIGHT DRIVE.

E. Philippiana and the glorious *E. macrantha* has some of the good points of both parents. It has the glossy evergreen foliage of *macrantha*, albeit immensely reduced in size, and the arching growth of *E. Philippiana*. The colour of the blossoms is a vivid salmony carmine very near to that of *E. macrantha*. For the benefit of those who neither know *E. langleyensis* nor *E. Philippiana*, it may be well to state that both have somewhat the habit of growth of *Berberis stenophylla*. *Cytisus præcox*, with its soft cream-of-sulphur coloured blossoms needs no description. The Mount Etna Broom, *Genista ætensis*, is not so much grown as it should be. It attains in time the stature of a small tree and is very handsome when in flower. The golden yellow blossoms are produced in July. *Prunus pendula* is an admirable weeping tree with multitudes of single cup-shaped rose flowers. It bears

extraordinary names in nursery catalogues sometimes. *Cerasus sinensis rosea pendula* may be taken as typical of such!

Philadelphia Lemoinei is here intended to cover any of Lemoinei's dwarf hybrids which may specially appeal to the planter. All are beautiful. *Cotoneaster frigida* is another species which seems undecided whether to be a shrub or a tree. It is attractive when in flower and very handsome when laden with its brilliant fruits, which in localities not too heavily stocked with birds remain until the new foliage breaks in spring. Birds will not take them unless very hard driven. *Magnolia stellata* is shewn underplanted with *Erica carnea*. Though very beautiful when in blossom, this *Magnolia* is rather sparse of habit and unattractive when out of flower. That dwarf Peach, *Prunus nana georgica*, is too seldom seen in gardens. For a short while

before the flowers expand the innumerable buds are a delightful and brilliant rose colour, quite surpassing those of *Prunus floribunda*. The trees for background might well be Scots Pines.

Fig. 2 suggests a layout for a pond-side shrub garden, and suggests how species of the different families may be grouped together, so that their several beauties may readily be compared. Such an arrangement has the added advantages of minimising work, since, as a rule, allied species like similar soils and general treatment, and require similar pruning. Best of all, such a grouping of species makes the whole garden interesting, no matter how extensive it may be, since each section visited is quite different from the last. In a subsequent issue it is proposed to take a section of the garden shewn and suggest detailed planting.

LATEST DEVELOPMENTS IN THE CHRYSANTHEMUM

THE development of the Chrysanthemum during the last three decades has been immense, but there are many who have not hesitated to express the opinion that a period of stagnation has arrived. No doubt there was a momentary check when the development of almost every practicable shade of colour in the huge exhibition mops had been completed. Since then, however, the raising of decorative sorts has gone on apace, and every year a number of good "market" varieties is certificated. There has, indeed, been a danger that "market variety" and "decorative" would become synonymous, but there are signs that this in future will not be the case. A market

flower must be stout of petal and compact, and must withstand rough usage without shedding. For home decoration, however, a more fragile flower answers perfectly, and, certainly, light-petalled varieties are likely to be more graceful and more easily arranged as cut flowers. The new sulphur yellow variety Wellington Wack, which is illustrated herewith, is interesting for the rigidity with which the rather narrow petals are held and the consequent spacing between them. The petals themselves are not nearly so fine as in varieties of the spidery petalled section (e.g., *Rayonnante*), yet the variety is so distinct as to be worth considering a typical variety of a new class. Shall we call it Golliwog-headed?

The other picture below shews a new "eyed" variety with several rows of petals. It might be said roughly to correspond to the peony-flowered section in Dahlias, but the perfectly clear eye and the good and neat habit of growth are, of course, points of advantage which this particular 'Mum has over the Dahlias. These "semi-single" forms will probably be useful to market men, for they should stand packing and travel better than the real singles. The variety illustrated rejoices in the name Alice Jinks, and is amaranth purple in colour.

There are great diversities of opinion as to what constitutes the most desirable type of single. There are those who consider *Mensa* the type of

THE SULPHUR YELLOW WELLINGTON WACK.

ALICE JINKS HAS SEVERAL ROWS OF AMARANTH PETALS

the ideal single. Evenly arranged *smoothly recurring* florets are their ideal. They may be taken to be a triumph of restful beauty. There are others—and the writer is one—who prefer the varieties of the Pagram family with very stiff but distinctly saucer-shaped flowers. There is less repose but more life in such a flower. Others, again, there are who, so that the eye be clear and shapely, most admire a variety with rather shaggy petals—such an one, in short, as Hilda Shoebridge, also one of this season's novelties and also illustrated. There is yet a fourth type which finds some admirers. The varieties which constitute it

CHRYSANTHEMUM HILDA SHOEBRIDGE, SOFT PINK.

might almost be called single incurved. Owing to the distinct inward rolling of the petals the flowers never appear very large, though if the petals are straightened out some of them are in fact, of very respectable size. Mary Richardson may be taken as typical of this style of flower. All these four types—and many varieties which will not exactly fit into any of them—are beautiful enough and useful. It is worth while calling attention to the diversity, however, if only to shew that there are more types of Chrysanthemum blossom than we are apt at first sight to think. The new anemone-flowered singles are also exceedingly beautiful alike for cut flower and for decoration in pots.

The popularity of the Chrysanthemum as judged by the recent show of the National Society is once again on the increase, and it is quite evident that the Society's executive will have to look about for a more commodious building than the Royal Horticultural Hall in which to house their exhibition.

NOTES ON SHRUBS for FAVOURED GARDENS

OF all the many species of *Acacia* that can be grown in favoured English gardens, none is more beautiful than the common one, *Baileyana*. Even if it never flowered it would be worth growing for its blue leaves, and its familiar "Mimosa" flower makes a yellow cloud in early spring in many Cornish gardens. In a quite cold house here one can have it in flower by Christmas. I have not yet seen *A. dealbata* as splendid in Cornwall as it is at Abbotsbury in Dorset, where it makes a huge tree. Like *Baileyana* this seems to require a good deal of shelter from wind if it is to flower well out of doors, but *A. longifolia*, though brittle, can stand quite a lot of wind.

Anopterns is rather disappointing, not nearly so fine as *Clethra arborea*, which it resembles in flower.

Buddleia madagascariensis, with orange plumes shaped like those of *B. variabilis*, grows with great vigour here, but I have not yet seen it profuse in flower, as on the Riviera.

The orange-scarlet bottle-brush flowers of *Beaufortia* can be grown here, but in their different season the *Callistemons* do the bottle-brush effect much better. The deep red *Callistemons* and the pale pink one with gold-dusted anthers, are magnificent.

There seems to be a better form of *Cytisus fragrans* than the one commonly grown in greenhouses up-country: this

and *C. stenopetalus*, and the slender white *C. nilitera*, are always worthy of a good place. There is, too, another white *Cytisus*, *C. proliferus*, which is a treasure for a wild garden: it makes a fast-growing tree with silvered leaves and with white flowers from winter to spring.

Clematis indivisa lobata, familiar in greenhouses up-country, is a wonderful sight in these parts in April, smothered in great white flower bunches. I feel sure, too, that when better forms of *Clematis Armandi* than those now commonly obtainable in commerce have been tried in gardens here, they will prove rivals or almost rivals to *indivisa*.

Why is not *Correa Harrisii* better known? Of all the *Correas* this is the most beautiful, more so even than the scarlet *cardinalis*. Its rose-red bells are borne for six months, from November onwards, and I have seen a large bush against a wall so streaming with them as to obscure the leaves. The plant is delightful for a pot indoors, tidy and perfect in habit. This is, I think, the best of the pink *Correas*, better than *ventricosa*. *Cardinalis*

is vivid and most beautiful, with the darkest green leaves as a foil for its flowers, but it seems to be a less hearty grower than *Harrisii* or the others. *C. alba* makes a nice greyish leaved plant for a shrubbery, and the ordinary *C. virens* is delightful in its quiet way. It has been hanging out its greenish white bells for some weeks already, and will go on doing so till May. It looks very well, I notice, in company with the tall green-flowered *Hellebore*.

Of the *Diosmas* that grow here in the open the most beautiful is certainly *D. uniflora*. This has solitary white flowers, rather like a *Flax*, over a round mounded bush. *D. gracilis*, with small white flowers, and *capitata*, with heads of mauve pink, are also pleasant shrubs to see, but the delight of *gracilis*, even more than the others, lies in the wonderfully aromatic scent of its bruised leaves.

Of the *Escallonias*, *macrantha* is, of course, the one most commonly grown here for shelter: it makes a splendid hedge 12ft. high and many feet through, and even now is plumed all over with its rose-red flowers shining in the glow of a November evening. From such short experience as I have had, however, I am inclined to think *E. exoniensis* makes an even more rapid screen than *macrantha* and deserves to be more widely used. Do other readers corroborate this, and do they find, what I believe to be the case, that seedlings of *E. macrantha* make better plants than cuttings will ever do? *E. floribunda* is delightful now, with a profusion of white flower heads, which are a favourite haunt of belated butterflies. *E. langleyensis*, that treasure worthy of any garden, is well known everywhere, but Edinburgh is quite as good and Donard Seedling very well worth a place.

Of *Erica melanthera* I have written before in these columns: the vigorous form of it, grown out of doors in some gardens here is certainly one of the noblest shrubs I have ever seen, far surpassing even *E. australis* at its best. It makes a great puff of mauve colour of rare waxy quality and in favourable conditions I have seen it over 12ft. high. In the correspondence recently about the "Twelve Best Shrubs," I was glad to see *Leptospermum Chapmanni* mentioned by at least one contributor. Yes, I quite agree. Anyone who has seen a big bush of this in full flower will never forget it and will always want to grow it.

Leonotis Leonurus grows well out of doors here, and is specially valuable for its late flowering; its tawny orange colour looks fine against grey wall or rock. I remember seeing beautiful photographs of Mr. William Robinson's of this plant, the Lion's Tail, growing in pots for the decoration of stone steps late in the year; I wonder that it is not more often used in this way, since it is easily propagated by cuttings and quickly reaches flowering size.

There are at least three sorts of *Metrosideros*, *tomentosa*, *robusta* and *diffusa*, which would be among the chief treasures of any garden. Unhappily they are too tender to be of use for any but the most favoured gardens out of doors. *Robusta*, I imagine, is the hardiest, and this flowers freely on the mainland in panicles of the splendid bottle-brush red. Like *tomentosa* it will stand any amount of wind; *tomentosa* does not suffer even from full exposure to the fiercest Atlantic gales. If only this were hardier it would certainly be regarded as one of the most valuable trees we have.

Z., Cornwall.

(To be concluded.)

TREES FOR THE WATERSIDE AND SWAMPY GROUND

IN these notes it is intended to draw attention to certain trees which thrive best by the waterside and in moist soils generally, rather than those suitable for widely different soils and positions. The selection of trees for planting in moist ground and swampy areas in ornamental planting contribute in no small degree to the beauty of the landscape. From the economic point of view there is often considerable opportunity for planting low-lying ground which is useless for farm or general forestry. The trees suitable for planting under these conditions chiefly belong to three families, the Alders, the Poplars and the Willows.

THE ALDERS.

The species of *Alnus* are widely distributed in four continents, Europe, Asia, Africa and America, generally fringing the banks of rivers and streams or growing in swamps and marshes. In some ways it seems remarkable that we are able to grow side by side in Britain with our native *Alnus glutinosa*, the Himalayan Alder (*A. nitida*), the Oregon Alder (*A. oregona*), the Caucasian Alder (*A. subcordata*) and the Japanese Alder (*A. japonica*).

Readily raised from seeds the Alders are fast-growing trees in wet situations. In the case of the varieties of *A. glutinosa* and *A. incana*, these can be propagated by layering, grafting on the Common Alder, or by cuttings inserted on a sheltered border during November.

A. glutinosa, our British Alder, is best known in gardens as the species from which several very ornamental trees originated. These include

var. *aurea*, a form with golden-yellow leaves; var. *imperialis* (*asplenifolia*), an attractive tree with deeply lobed leaves; var. *laciniata*, also with lobed leaves, but not so deeply cut as the last named; var. *quercifolia*, leaves resembling those of our Common Oak, and var. *rubrinervia*, a form with red leaf stalks and veins.

A. incana, the speckled or grey Alder, is a widely distributed tree in the North Temperate Zone. With a smooth greyish bark and a grey-green undersurface of the leaves, it is a more attractive tree than the Common Alder. There are a number of varieties, the best and most distinct being var. *aurea*, yellow twigs and leaves; var. *incisa* (syns. *laciniata*, *pinnatifida*), a beautiful cut-leaved Alder for the lake side; var. *monstrosa*, having fasciated branches and fruits, novel and interesting; var. *pendula*, a very handsome tree with weeping branches; var. *ramulis coccineis*, a very distinct tree when leafless in winter and spring, with red young twigs and catkins.

A. elliptica, the hybrid Alder; there is a fine specimen of this fast-growing tree by the lake side at Kew, about 75ft. high. It is a natural hybrid between *A. cordifolia* and *A. glutinosa*, found in Corsica. The cultivation of this tree for its timber is worth considering, for it is well known that, for the soles of clogs, Alder wood has no equal.

A. cordifolia, the Italian Alder, though a south European tree, is perfectly hardy and of fine, upright growth. An attractive specimen tree in front of the Economic Museum No. 1 at Kew on the bank of the pond, exceeds 70ft. in height.

A. nitida, the Himalayan Alder, I should be inclined to place first among Alder species as an ornamental tree, though in time it may be rivalled by two new ones from China, *A. cr-mastogyne* and *A. lanata*. Native trees reach 100ft. in height and several trees at Kew raised from seeds in 1882 exceed 50ft. The leaves are 4ins. to 6ins. long and half as wide.

If space permits *A. firma*, *oregona*, *orientalis*, *subcordata*, *molis* and *japonica* are all worthy of attention in addition to those already described.

THE WILLOWS.

The value of Willows for waterside planting is too well known to need extolling to readers of THE GARDEN. Among such a large number of species, varieties and hybrids it will be possible to draw attention only to a few of the best.

The most beautiful of all is undoubtedly Napoleon's Weeping Willow, *Salix babylonica*, a wide-spreading tree of great beauty. *S. Salomon* is a hybrid between *S. alba* and *S. babylonica*, the branchlets are not so drooping as the last named, but it is a very graceful and noble looking tree. *S. vitellina*, the Golden Willow, is a handsome tree, abundantly furnished with twigs which in sunshine, shew brilliant yellow when leafless in winter. *S. alba*, the White Willow, is a beautiful native tree, fringing the banks of our rivers in many places. The variety *argentea* (syn. *S. regalis*) has leaves of a shining silvery hue which are distinctly ornamental. *S. corulea*, the Cricket Bat Willow, is a fast-growing upright tree and a

THE DECIDUOUS CYPRESS, TAXODIUM DISTICHUM

A GOLDEN WEEPING WILLOW, SALIX VITELLINA PENDULA

most valuable timber tree to plant in wet ground. The name "cœrulea," or the Blue Willow, is given because, seen at a distance, the tree has a blue-green appearance, due to the blue-grey undersides of the leaves. *S. fragilis*, the Crack Willow, distinguished by the readiness with which the twigs crack, forms a large wide-spreading, bushy-headed tree. The Bay-leaved Willow, *S. pentandra*, is one of the most distinct and ornamental of our native Willows. More often a bush than a small tree, it can be readily pruned to grow into an attractive tree, 30ft. to 40ft. or even 50ft. in height. Large for a Willow—hence the name "Bay-leaved"—the rich green leaves are from 2ins. to 4½ins. long and half as wide.

THE DECIDUOUS CYPRESS.

Taxodium distichum is one of the most distinct and attractive trees we have for the waterside. At Syon House, Middlesex, a place famed for its large specimen trees, there are several *Taxodiums* by the side of the lake over roof-t. Here they produce the curious woody protuberances or "knees, from the roots above the ground, which we read of their possessing in the native swamps of

the southern United States. The attractive features of the tree are its tall pyramidal habit and leathery foliage, light green in summer, changing to rich brown before falling in autumn.

THE COMMON ELDER

Sambucus nigra is usually relegated to out-of-the-way neglected spots because it has a habit of springing up, wherever it can get root-hold, through birds spreading the seeds. A well grown tree of the Elder, however, with a clean trunk of 8ft. or oft., and some 20ft. to 25ft. in height, is a distinctly attractive flowering tree by the waterside about mid-summer.

THE SITKA SPRUCE

Picea sitchensis is one of the best evergreen conifers for wet ground, both as an isolated tree for ornamental purposes and closely planted as a commercial timber tree. In Scotland there are trees over roof-t. in height. Several years ago Mr. William Robinson was loud in his praises of this Spruce which, in moist ground, was making splendid growth with him at Gravetye, Sussex. A. O.

MICHAELMAS DAISIES—II

THE Editor has very kindly granted my request, so I am off again. I would never have ventured to ask for another turn, only I feel that it is not sufficiently realised what a splendid autumn flower the Michaelmas Daisy has become. There are shapes, habits and colours galore to be found

among its many species and hybrids. One or another gives us three months of flowers. The bunch of Belgian Queen, The Queen, Ringdove and some late bits of Climax that I brought into the house on Armistice Day speaks equally eloquently of the hardiness of the race and the long period of its usefulness. Since then I have

seen the splendid show of the *Chrysanthemum* Society in the R.H.S. Hall at Vincent Square. I had to rub my eyes as I stood before Jones' mammoth exhibit of beautiful blooms of almost every type the *Chrysanthemum* can give us, to make sure that I was not in some corner of an unearthly Paradise. I had to perform the same rite before the "vegetable marvels" of patient care and industry that filled the long lines of show boxes. I saw the abomination of disbudding in the swollen heads of my old friends the ancient Pompons. It was all very wonderful, but never, even for the smallest fraction of time that human ingenuity can measure, did I feel inclined to desert or to be dissatisfied with my Michaelmas Daisies at home. Of course I should be sorry to be without any Dahlias, and I gladly own that early-flowering *Chrysanthemums* have their uses, but neither the one nor the other are to me quite like Michaelmas Daisies. My first article was almost entirely confined to notes about varieties in my favourite section, the Novi-Belgii. I concluded

by mentioning two very beautiful ones of the cordifolius section, Little Bo-Peep and elegans. Oh! these other sections! Botanists are perhaps necessary evils, and I do try to think of them with kindly feelings, but when I picture the enjoyment they seem to get out of such a family as that of these perennial *Asters* and compare it with the slough of despair that they are to myself, I do what the tale avers Bishop Magee of Peterborough did when a waiter upset the sauce over his coat, I ask some layman to make an appropriate remark. I go a step further than Bailey's *Cyclopaedia*, which says of all these species that they are "botanically confused"; they are, I fear, horticulturally mixed too. Such being the case, the best way out of the difficulty is to mention the source from whence the plants came that I am going to bring before my readers.

Of all the many smaller fry in my collection none was more admired than diffusus *Bianca* (Wells of Merstham and H. J. Jones). If horizontalis is a synonym of diffusus, this example bears the idea out. More than one visitor described it as a 4ft. high Cedar of Lebanon made out of a small-leaved and daisy-flowered *Michaelmas Daisy*. The branches laden with innumerable white flowers come off from the central stem at right angles and so set up the resemblance. Without elbow-room it would be nothing. Hence it has occurred to me that a clump of three to five would make a capital and uncommon isolated bed on grass. Goldfinch (Beckett) and Star Shower (Amos Perry) to some extent feature *Bianca*, but they are not nearly so important-looking and are, I see, placed in the *ericoides* section, which means they are slighter in build and have smaller flowers. The true companion of *Bianca* is probably the Hon. Vicary Gibbs, with the pure white flowers turned into a decided lavender. It was, I regret to say, one of the varieties which did not do as well as they might have done, so I can only say it will surprise me if it is not very nearly a second *Bianca*. To revert again to Bo-Peep, my favourite of the feathery-flowered cordifolius type, I would mention *Diana* as a second string if Bo-Peep cannot be had, for I cannot find it in the newest lists which have just come to hand.

Decorator and Delight (both Perry) are two good ones of the *ericoides* section, and compacta alba (Jones) is my favourite among the vinaceous section. It now only remains for me to mention a few odd varieties which commend themselves for particular idiosyncrasies. For a cannon ball of bloom like the well known St. Egwin we have an excellent representative in the fine pale pink Namur (Barr) and one of my own seedlings, Redbrook, a pretty shade of mauve. They are not my fancy at all, but ever since a gardening friend came and picked out the last named as the one he liked the best, I feel bound to mention them. They do make good blobs of bloom. *Cattleya* (Jones) is a semi-double of great charm. Everyone, including myself, gives this soft rosy pink a pat on the back. Roddy (Wells) has, as far as my experience goes, one dreadful drawback. It suffers from spinal curvature, and, unless every inch of the main stem is supported, over it goes. Its individual flowers are so pretty and delicate-looking with their almost white halo round the central yellow boss and their soft rosy petals that it is well worth while taking pains with it in order to use the little side branches for cutting.

R. E. Hay, which came to me from another source, appears to be the same thing. Bruges (Jones) is almost a "cannon-ball." Its pale lavender flowers are so many and so big that you just have to notice it. Many of the individual blooms are a good 2½ins. in diameter, but the yellow centres are sadly disturbed by so many of the disc florets becoming dissatisfied with their lot and

A CEDAR-TREE TYPE OF MICHAELMAS DAISY OF WHICH BIANCA IS A FINE EXAMPLE

half-heartedly apeing the dress of those which rightly compose the ray. My last variety (or species?) to mention is a very late daisy-flowered one that came to me under the name of *ericoides* var. *diffusus* (J. C. House). It might almost be described like the one that Mr. Bowles in his book "My Garden in Autumn" heard described as an *Asparagus* plant with lots of white Daisies stuck all over it. It is very light-looking, and so is very handy for cutting, more particularly because it is so late to flower. Here only *Tradescantia* is behind it. At the time of writing (Novem-

ber 20) there is not one flower open. This leads me to ask the question, How do Michaelmas Daisies fare if the plants are lifted with a good ball of roots and then potted and placed in a cold house in the same way as *Chrysanthemums*? I have been told that some such proceeding is the secret of some of the splendid displays that greet us at shows, and I have recently read about lifting in private gardens. Can anyone give us the A B C of how it is done? By analogy it looks a very simple thing to do, but one never knows. JOSEPH JACOB.

Rutland where the plant grows freely in the ordinary loam, which is naturally limy, as I have never seen it grow anywhere else. There is a bold edging of it all round the carriage drive, in full sun. This is exceptional and anyway I like the plant best smuggling among big grey rocks. Stevenage. CLARENC ELLIOTT.

THE USE OF NURSE PLANTS

MOST practical gardeners know full well how certain plants dislike isolation and under some conditions positively refuse to prosper until given suitable companionship. *Gentiana verna* might be given as an example of one of these, and I have known patient amateur gardeners fail for years to satisfy this charming species until, by accident or design, the plants became more or less grown-over by some other lowly plant, when they immediately did satisfactorily.

The explanation why such plants, perhaps the majority, flourish better with companionship is doubtless more or less directly connected with moisture supply. Soil that is covered, being less liable to suffer from rapid evaporation, is maintained in a more equable condition than that which is fully exposed to the direct rays of the sun and sweeping winds. Habit, or what one might even call temperament, is also a factor to be reckoned with sometimes, some plants appearing to sulk from sheer loneliness.

For several years I have made a regular practice of using nurse plants in all cases where their presence seemed desirable, and with most satisfactory results. With such things as Heaths, for example, which are always apt to suffer during their first summer in our hot shaley loam, a partial smothering with some suitable annual sown all over the patch will not only prevent many a plant from succumbing, but actually encourage growth. Moreover, the nurse plant, if chosen with discretion, will often give beauty to a spot which is usually anything but pleasing to look upon during the first season or two.

Among the most suitable annuals for companionship newly planted Heaths, more especially on dry banks where a sheltering growth is most essential, one might mention the *Collinsias*, the large-flowered blue and white, purple and white or pure white being of suitable habit and stature as well as extremely pretty. The Candytufts, especially the lilac variety, are also admirable for such use. *Mignonette* can also be employed for this purpose, and for smaller-growing things than Heaths the dwarf annual *Alyssum*, called, I believe, *Lilac Queen*, is first-rate. But I need hardly say that there is an infinite choice of adaptable annuals for employing in this way—easy culture, with fitting height, habit and colour being the chief desiderata.

Considerably more discretion must, of course, be exercised in selecting companion plants (not necessarily annuals) for the smaller *Gentians*, *Soldanellas* and such like, for with these latter one must not use anything whose colour would be liable to detract from that of the plants we are endeavouring to succour. In our own garden we have no difficulty in choosing company for any of the smaller alpinæ we wish to treat in this manner, for a little white Herb Robert *Cranesbill*, smaller and more refined in all its parts than the native species, grows freely everywhere, and nothing could suit better the purpose in view. Failing that, one could employ the *Violet Cress* (*Ionopsidium acaule*), *Mentha Requieni*, *Androsace lactiflora*, *Veronica filifolia*, *Tunica saxifraga*,

A CHARMING ALPINE

THAT rarest and most beautiful of the Navelworts, *Omphalodes Luciliæ*, has a great reputation as a difficult plant, and certainly when I first tried to grow it, many years ago, it did not shew any great enthusiasm for my blandishments. I put it in the first funny little moraine that I ever had. This was

till early autumn, the plants carry a succession, sometimes a multitude, sometimes just a few and then a multitude again, of giant forget-me-not flowers, as big as sixpences, of a delicious soft clear lavender blue.

The grey smooth leaves make as perfect a setting for the soft blue flowers as the quiet grey

MR. ELLIOTT'S COLONY OF *OMPHALODES LUCILIÆ*.

an affair of granite whose chief and only merit was that its rough surface discouraged the promenading of slugs. There, in full sun, and deprived of lime, sat *Omphalodes Luciliæ*, a stunted invalid. Then one day I got a broad hint as to what the plant really likes. In full shade under a north wall on a silly little heap of bricks and mortar, especially mortar, I saw *Omphalodes* flowering and flourishing rampantly. Lime and shade! The exact opposites of what I had been providing! The hint was too broad to miss; and I had at Stevenage the very place to try the experiment, on a newly made limestone moraine rock garden. At the northern end and sloping to the north was a broad comfortable run of limestone moraine mixture between grey water-worn rocks. I dug up my old sun-stunted plant, pulled it ruthlessly to pieces, making half a dozen well rooted divisions and planted them in their cool limestone home. The improvement was immediate and quite remarkable. Every piece took hold at once and set to work to grow with real enthusiasm and they have flourished increasingly for the last eight or nine years. What a lovely plant it is when healthy and given a good setting. Here the leaves are big and fat and of a pleasing Quaker grey and from May onward, right through summer

rocks make for the whole plant. Not only does my colony of *Omphalodes Luciliæ* flourish and flower, it sets good crops of seeds and these have given me young plants which I grow in small pots with quantities of lime chips in the soil. Self-sown seedlings, too, spring up spontaneously among the old plants.

There is a tradition among garden writers that slugs have a passion for this plant and will travel enormous distances to obtain it. My own experience of slugs teaches me that they are very whimsical creatures. They will go to any lengths to obtain a certain plant in our neighbourhood, while the slugs of the next parish would not thank you for it. The Stevenage slugs are quite unconventional as regards the pleasures of the table. They would not cross the street for *Omphalodes Luciliæ*; they do not care a rap for *Aster alpinus*, are apparently quite unbiassed by the catalogue value of the plants they eat and they seem to ignore all those plants which journalists have done so much to popularise among the slugs of this country.

I give my hint of shade and lime for *Omphalodes Luciliæ* for what it is worth. It works here like magic, as is shown in the accompanying photograph of part of my colony. But I know a garden in

Petrocallis pyrenaica, *Oenothera pumila*, the *Globularia* or *Mazus*. There is, indeed, a host of first-rate little plants admirably suited to accompany the choicer and more difficult things, and were these more commonly used as nurse plants or as a carpeting one feels convinced that they would not only help many an amateur out of the problem as to how he can better please his more obstinate favourites, but they would at the same time render the almost naked soil "pockets" one sees in so many rock gardens much more attractive.

A. T. J.

THE KALMIAS

NO one engaged in planting *Rhododendrons*, *Heaths* and other peat shrubs should overlook the claims of the small but select genus *Kalmia*, of which *K. latifolia* is the finest and easiest. This North American species, with its broad, *Rhododendron*-like leaves, is usually seen as a shrub of about 4ft. in height, and it is accommodating enough to thrive on any good lime-free loam as freely as it does in peat. The largest specimens of this kind, one which it has been my good fortune to see in full flower every season for many years, is growing in ordinary yellow loam, and it has attained a stature of some 6ft., the diameter at the base being quite as much. This shrub is, on reliable testimony, not less than 100 years old, and it is growing on a lawn with full exposure.

The large, pentangular flowers of *K. latifolia* are borne in abundant terminal clusters in May. They are of a peculiarly waxy texture, and in the ordinary type are vivid coral red in the bud, opening to a pale rose pink which passes into white. In some forms, however, the blossoms are of a richer colour, the full-blown flower retaining the characteristic brilliance of the bud stage. But all varieties are first-rate and never fail to attract considerable attention. When planting *K. latifolia* in districts where peat does not exist a little leaf-mould should be worked in about the roots, and old cow-manure in early spring is highly beneficial.

Though *K. latifolia* excels all others in size and beauty of blossom, no less than in ease of culture, the smaller *K. angustifolia* should always be given a space where suitable conditions exist. This is a very charming little bush of about 2ft. or more, with smaller, blunter leaves than the above. The flowers are rosy pink, saucer-shaped and appear at the tips of the branches in early June. The flowering season of this species, however, seems to vary considerably with weather conditions or locality, and the beautiful crimson variety, *K. a. rubra*, is often an autumn bloomer. There was a group of this latter form in full blossom at Kew in the second week of October last, but none of the other kinds which I saw in those gardens had a flower to show. There is a true alpine form of *K. angustifolia* which I came across growing near Lake Louise in the Rocky Mountains a few years ago, an exceedingly pretty dwarf trailer with brilliant crimson flowers. This I have failed to discover in the lists of English nurserymen, though it is doubtless obtainable.

K. glauca is a narrow, greyish-leaved little shrub of 18ins. or so, though old plants may be found of considerably greater height. The flowers (June) are about half an inch across, of the same general pattern as those of the other species, and of a deep satiny pink. Both *KK. angustifolia* and *glauca* appear to be rather more

impatient of drought than *K. latifolia*, and it is probably on that account that they do not always prosper so well in loam as the last named. An atmosphere inclined to humidity is also a desirable feature. For these reasons a mixture of

leaf-mould, peat and old cow-manure may be used where the natural soil is not of the best, and the site chosen should be one that is fairly cool and moist, yet freely drained and screened from the midday sun and high winds. J.

A SELECTION OF FUCHSIAS

THE following brief notes on the behaviour and merits of the various varieties of *Fuchsias* grown here during the season just ended may perhaps be of interest to some of the many readers of *THE GARDEN*, and also, I hope, may be of help to some who are contemplating taking up the cultivation of this beautiful and easily grown cool greenhouse plant.

The summer of 1922 can hardly be said to have been a good one for the *Fuchsia* as, with us at least, the flowers and buds were inclined to drop and damp off owing to the unusually damp atmosphere and lack of sunshine. The gem of our collection was undoubtedly *Jeanne d'Arc*, and at the present time (October 25th) it is still flowering. The colourings of this variety are very beautiful, the reflexed sepals being broad and of a beautiful soft pink shade, while the corolla, when the flower first opens, is of a deep blue tone, changing in the older flowers to a rosy lilac; it is one of the earliest to bloom and is free flowering, almost to a fault, as it is very difficult to get cuttings from it on that account.

Isabelle is another very beautiful sort, bearing huge double flowers which hang in clusters at the ends of the growths. The sepals are carmine and the corolla is pure white veined carmine. *Elsa* is of somewhat similar colouring to *Jeanne d'Arc*, though the sepals are paler in colour and the corolla is more of a reddish violet shade, while the flowers, though larger individually, are not produced nearly so freely or continuously and, in the writer's opinion, are not of such good shape. *Mauve Beauty* was grown here for the first time this year and has quickly established itself in favour; the double corolla is of a very beautiful shade of mauve or pastel pink and the horizontal sepals are of a very deep red. *White Queen* was one of the earliest to flower and was very beautiful during the month of June; it is a single *Fuchsia* with long tube and white horizontal sepals, while the corolla is vermilion; the foliage is large and of a deep green, shaded bronze. *Prince of Orange* is another single that is worth a place in any collection, in fact I should be inclined to choose it in preference to *White Queen* as it is more continuous in flowering; the tube and sepals are short and broad and are shaded with orange, while the corolla is of a very rich orange-red shade. *Earl of Beaconsfield* is of somewhat similar though lighter colouring, but the tubes are very long and the individual flowers are smaller. *Swanley Yellow* is another fine single of similar type, but the small flowers have corollas of a much more yellow shade; the foliage is exceedingly handsome being very broad and of a deep sage green colour.

Rose of Castille is an old free-flowering sort of red and purple hues and is still well worth growing. *Pink Paul* is a variety that was introduced by Mr. H. J. Jones, Ryecroft Nurseries, in 1921, and the name is fairly descriptive of the colour; the flowers are not large, and the sepals and semi-double or double corolla are of a deep pink shade, while the foliage is dull green and velvety to the touch. *Princess Dollar* is a very free-flowering variety that is really useful for indoor decoration on account of its compact bushy habit of growth; the flowers are small, but very bright, the double

corolla being of a deep violet shade, while the sepals are carmine-red. *Avalanche* is an old favourite of similar colouring to *Princess Dollar*, but, unlike that variety, the flowers are very large while the foliage is shaded with golden bronze.

Pasteur is a fine double sort that bears large flowers in great profusion; the sepals are red and the corolla is greyish white, heavily veined with red. *Rolla* is one of the more delicately coloured *Fuchsias* and is certainly very beautiful; the double corolla is white and the sepals are of a soft salmon pink. Both contrast well with the handsome deep green foliage.

A very fine *Fuchsia* with ornamental foliage is *Thalia*, a hybrid from *F. triphylla*; the leaves are large and velvety and of a deep bronze shade while the tiny trumpet-shaped flowers are carried in clusters and are bright orange red in colour, making a fine contrast. *Sunray* is another beautiful variety that has foliage of a pretty combination of cream, rosy salmon and soft green, while *Wave of Life* has bright golden foliage and is a useful variety for summer bedding.

All the above mentioned *Fuchsias* can be strongly recommended to anyone desirous of starting a collection, although I am quite well aware of the fact that I have probably omitted many varieties that another grower would recommend and it would be of interest if some other amateurs would contribute a few notes on their favourite varieties, as it is seldom that there is any correspondence on this beautiful and easily grown plant. In conclusion I will give a list of what I consider the best twelve sorts, taken from those mentioned, for anyone about to start their cultivation and will place them in order of merit so that it may perhaps be of help where less than a dozen are required. *Jeanne d'Arc*, *Isabelle*, *Prince of Orange*, *Avalanche*, *Rolla*, *White Queen*, *Elsa*, *Pasteur*, *Mauve Beauty*, *Princess Dollar*, *Thalia* and *Swanley Yellow*. The above selection gives a wide range of colour and also diversity of type, so that it should contain varieties that will appeal to all.

Belfast.

CECIL M. BAILEY.

THE ORNAMENTAL CRABS

AN important point about these very beautiful and interesting trees is the length of time during which their fruits remain ornamental or, indeed, remain on the tree at all. The forms and hybrids of the Siberian Crab, which are the only ones at all palatable in a raw state, do not remain long on the branches when ripe. Their fruits, moreover, are very attractive to birds. The forms of *Pyrus Malus* on the other hand are usually very sour and little to the liking even of the hungry starling. *Pyrus spectabilis* is an unpalatable species, so is *P. Niedzwetzkyana* and the same may be said of their delightful hybrid, *P. Eleyi*. The parentage of *P. Eleyi* was, by inadvertence, wrongly given in *THE GARDEN* for October 28, page 537, *P. floribunda* being mentioned as one parent instead of *P. spectabilis*. *Pyrus Ringo* is less attractive than some to birds because of its yellow colouring. Otherwise, no doubt, the fruits would quickly vanish as it is not at all bad eating.

OCTOBER IN A WEST SOMERSET GARDEN

USUALLY one of the most enjoyable months of the year in the mild South-West, October, this year was notable mainly for unfavourable climatic conditions. With the exception of two or three days early in the month, there was practically no sunshine, a bitter north-east wind having been much in evidence. Still, the garden from which I am writing lies in a fairly sheltered spot near the sea, and despite frosts and winds there has been quite a fair display of blossom of various sorts.

Even in November *Buddleia auriculata* scented the air with fragrance from its small cream-coloured flowers, and made such strong growth that it had frequently to be hard pruned to keep it within bounds. It succeeds well here both on a wall and as a bush, and is much hardier than *B. asiatica*, with which it has often been confused. In the early part of October there were still flowers on a very beautiful form of *B. variabilis*, which was collected in China by Farrer and is apparently unnamed as yet; its semi-pendent habit and smaller, neater growth than the type renders it most attractive for small gardens. Lack of sun retarded the colouring of the *Berberis*, both as regards foliage and fruit, though *Berberis yunnanensis* already had some vivid scarlet leaves. *B. Wilsonæ*, *B. subcaulilata* and *B. polyantha* flowered much later than usual, consequently we could not expect much shew of berries till later autumn. On a low wall facing south *Cassia corymbosa* was a beautiful sight for many weeks; its deep golden yellow flowers shew up so well against the shining green foliage. It is making such strong growth that it threatens to smother its neighbour, *Feijoa Sellowiana*, which was badly broken by a heavy snowfall last April. The lovely *Lonicera Hildebrandtii* on the same wall still bears a few of its giant Honeysuckle blooms, but is happier in a more sunny season. It is growing entangled with that rampant Brazilian *Araujia sericifera*, which was a mass of flower, but failed to set fruit this year as it did last season. Near by a pretty picture was formed by the dainty Australian *Sollya heterophylla*, whose lovely blue flowers on thread-like stalks appear here and there in the midst of that wonderful Chinese Vine, *Vitis Henryana*, one of the most exquisite of all plants in its autumn livery.

Rosa Moyesii, grown in three years to a large plant armed with fearsome thorns, is as beautiful with its vivid scarlet hips as it was in June when the great ruby Roses were at the height of their glory. In front of the Rose is another berry-bearer of a very different type, the New Zealand *Hymenanthera crassifolia*, a box-like shrub allied to the Violet, laden with tiny piebald berries unlike those of any other plant I know.

In early October *Ceratostigma Willmottianum* was still very charming with its exquisite blue plumbago-like flowers, but the bitter winds soon chilled them and made them look pale and washy. *Lithospermum rosmarinifolium* had already begun

to put forth its incomparable deep blue flowers, and will continue to do so throughout the winter unless the elements prove especially unkind to this treasure from sunny Capri. *Leptodermis pilosa*, somewhat of a new-comer from China, still kept up a succession of small pale lilac trumpets, perhaps more appreciated in autumn than among the summer wealth of blossom. Sheltered by the silvery thicket of *Convolvulus Cneorum* a young plant of *Polygala ruscifolia* has flowered steadily for the last three months, its purple pea-like flowers rendered very charming by the curious white brush-like stamens which protrude from the lower wings. Here, too, nestles *Chorizema cordatum*, another choice Australian,

FRUITS AND FLOWERS OF FUCHSIA PROCUMBENS.

well set with buds for a display early in spring—it frosts permit. The Pomegranate (*Punica granatum*) has been flowering in a mild way for some months, probably encouraged by last year's roasting, but though it grows fast enough and is apparently perfectly hardy, it does not seem to wish to give us its flowers with any lavishness. Lack of sun this year is no doubt the reason for the non-flowering of *Bomarea multiflora*, that glorious climbing *Alstromeria* which annually sends up 12ft. shoots through a tangle of white *Cianthus puniceus* and *Rosa sinica* *Anemone*. *Abutilon megalopanicum* still swung gold and crimson lanterns from its slender branches, and is one of those shrubs which looks far more tender than it is in reality. It is a very rampant grower and bears cutting back well.

Myrtus Ugni was laden with crimson fruits, not yet ripe, with their delicious strawberry flavour, but very beautiful and distinct from other shrubs,

The shrubby *Pentstemon cordifolius* still bore some of its showy crimson flowers, so unlike the familiar species of this great genus. Another plant which always perplexes those who have not met with it before is the red and yellow *Lobelia Cavanillesii*, with buds resembling the head of a toucan and very far removed in appearance from the bedding *Lobelias*.

The *Fuchsias* continue to flower well in this neighbourhood until winter has definitely arrived. During October none was more charming than a hybrid called *Venusta* with very long, tubular blooms, but it is tender and gets cut to the ground in most winters. The tiny flowered *F. Cottinghami* was laden with scarlet flowers, and is quite one of the most desirable of all *Fuchsias*. *F. procumbens* from New Zealand has enjoyed the damp of this year, and its prostrate stems are laden with purplish crimson fruits and quaint blue-anthered blossoms. For long-continued flowering *Diplacus glutinosus* is one of the best plants I know, and cuttings struck in autumn make nice little shrubs the following season. The dark red variety and the ordinary buff-coloured one are equally satisfactory in the Western Counties. *Salvias*, of course, are invaluable for autumn colour. Most precious of all in mild districts is the glowing scarlet *S. fulgens*, which is quite hardy here. From cuttings struck in September of last year we have had bushes 6ft. high, a mass of bloom from top to bottom. *S. Grahami* is a much smaller-growing shrub, at least as hardy and of great beauty, and the Pineapple *Salvia* (*S. rutilans*) is now in flower, an old plant being about 7ft. high. *S. coccinea* is very vivid in hue, but too tender to winter unprotected outdoors, though this year some self-sown seedlings have come up and have flowered. *S. patens* is unrivalled among the true blue flowers of autumn, and the newer *S. uliginosa* is very valuable for its tall habit and spikes of clear blue flowers at this season. It is a better plant than *S. azurea grandiflora*, with which it is much confused.

Another beautiful mass of blue was conspicuous in the border where a group of *Pentstemon heterophyllus* had flowered persistently since June. *Cuphea ignea* is yet another wonder for flowering over a long period, and is most attractive in a mass and when the individual flower is closely examined—opinion being divided as to whether it more resembles a cat or a shrimp!

In the rock garden a good many plants continued to flower as merrily as in summer. *Androsace lanuginosa* being very lovely. This is quite one of the most beautiful and lasting of rock plants. The intense blue of *Lithospermum prostratum* contrasted well with the equally vivid scarlet of *Verbena chamaedrifolia*, which has run far beyond its allotted home and invaded both *Lithospermum* and *Androsace* territories. *Arenaria grandiflora* had a profusion of its large white blooms, quite reminiscent of the spring, but *Parochetus communis* was only just shewing its exquisite blue pea flowers amid its dainty trefoil leaves. A dull, damp summer agrees well with this moisture-loving Himalayan, which soon perishes in a scorching season unless freely watered. The noble foliage of *Geranium anemonifolium* gives welcome shade and shelter to that charming wee trailer *Gaithera trichophylla*, whose amazingly large berries were just beginning to assume their unique blue shades, almost suggestive of some strange birds' eggs lying on the tiny stems and deep green leaves.

Irises, too, have been helping to bring interest to the autumn garden, Mrs. Alan Gray in particular bearing many fine stems. *I. unguicularis* had begun to flower, and will keep up a succession till next April. N. G. HADDEN.

CORRESPONDENCE

ROSE TEST GARDENS.

YOUR readers may be interested to know that my Council had recently under consideration the question of the setting up by amateur rosarians of Rose test gardens in different parts of the country. The Council on October 30 last unanimously passed the following resolution: "That if and when a trial garden for Roses is set up by

lanceolate, while the stem leaves are long and sessile. It appears to be rare in Switzerland, growing only on some of the Southern Alps in Valois on the Italian Frontier, is also a native on the Alps of Savoy and Dauphiné in Italy, in Bosnia and Montenegro. It is said only to grow in stony silicious rock and is very local, but from the way it grows here in soil that contains lime

AN UNUSUAL CATCHFLY, *SILENE VALLESIA*.

the National Rose Society, such garden shall be run by and under the direct control of the Society."—COURTNEY PAGE, *Hon. Secretary, National Rose Society.*

A NEW BARBERRY.

ON October 31 a hybrid *Berberis* received an award of merit from the Floral Committee of the Royal Horticultural Society when shewn under the name of Lady Beatrice Stanley. It was, however, not Lady Stanley's intention that the *Berberis* should bear her name, and the Committee has agreed that it should be called in future Sibbertoft Coral.—W. R. DYKES, *Secretary, Royal Horticultural Society.*

AN UNCOMMON BUT EASY ALPINE.

SILENE VALLESIA is spoken of as rare. It certainly does not appear to be very common in gardens, but although perhaps not so brightly coloured as some, it is one of the most desirable of the Catchflies. It is quite robust and spreads freely, but only grows about 4ins. high. It has viscid pubescent stems which are assurgent and slightly branched. The flowers, which are borne in May and June, are long-peduncled, terminal, rarely in pairs. The corolla with bud segments, the tips of which soon curve, is of a lilac-rose colour, while the colour below is of a brick red. The large, tubular, elongated calyx, bulging like a vase, glandular and pubescent, somewhat inflated after anthesis, is whitish striped with red, and shows up against the bright green foliage. Some of the lowest leaves are spatulate, others

it should grow in almost any soil. It is seen at its best in early morning, for, like some other members of the genus, it is often closed during the brighter part of the day, but even then the striped inflated calyx is quite attractive. It is readily grown from seed or pieces taken up soon grow and make a good clump.—F. G. PRESTON, *Botanic Garden, Cambridge.*

TWELVE BEST SHRUBS.

NO doubt every reader of THE GARDEN is an ardent admirer of flowering shrubs and has been much tempted to send you his or her views as to the best. If you are not—though I expect you are—already overburdened with suggestions, I offer the following: *Spring*.—1, Darwin's Barberry (or *stenophylla*); 2, a Weigela (or dark red *Ribes*); 3, *Forsythia suspensa* (or a *Cydonia*). *Summer*.—1, *Philadelphus grandiflorus* (or *Lemoinei*); 2, *Escallonia macrantha* (or *Kalmia latifolia*); 3, *Hydrangea hortensis* (or Tree Peony). *Autumn*.—1, Spanish Broom; 2, *Buddleia superba*; 3, *Tamarix hispida vestivals* (or a *Veronica*). *Winter*.—1, *Hamamelis mollis*; 2, one of the new coral fruiting Barberries (or *Pernettya*); 3, *Skimmia japonica* (male and female). I take it no one asks advice as to ordinary cottage garden indispensables, such as Rose, Lilac, Laburnum, Lavender, etc., or regarding such well known but special types as *Rhododendron*, *Azalea* and *Rock Rose*. Also it would hardly be wise to exclude the all-round good shrubs for the sake of the tropical beauty of such as *Crinodendron*, *Andromeda*, *Fabiana*, etc., which must have suitable soil and locality.—E. T. PAUL.

A FINE ANEMONE.

IN the article on Anemones in the issue dated November 18, no mention is made of that excellent variety *Anemone Mallenderi*. It is one of the very best of all the *Pulsatillas* on account of its splendid rich purple flowers. It was raised by Mr. J. Mallender of Scrooby, near Bawtry, and is a reputed cross between *Pulsatilla montana*. There are two distinct strains, one with more blue and the other with more red or claret in the purple. Anyone who has seen the long beds of it at Scrooby as I have done could not fail to be impressed by its rich magnificence.—JOSEPH JACOB.

LATE STRAWBERRIES.

I ENCLOSE a small bunch of Royal Sovereign Strawberries which I picked this morning (Nov. 19) in my kitchen garden. Is not this extraordinarily late in the year for a Strawberry practically to ripen out of doors.—J. A. BLISS.

[The fruits sent were full grown and one had changed colour. Such late fruits are more common after dry summers than wet ones. There are, of course, varieties of which late fruits may be relied upon, but Royal Sovereign is not one of these.—ED.]

WHAT BECAME OF THE GRAPES?

I SEE in THE GARDEN of October 28, in your account of the Royal Horticultural Society's Show on October 17, "According to the official list of awards Lady Margaret Bickersteth was awarded a card of cultural commendation for Sultana Grapes, but search and enquiry failed to discover them."

I shall be very glad if you can help to unravel the mystery which surrounds this exhibit. I helped my mother to pack two magnificent bunches, weighing together, if I remember right, about 9lb. We are not, of course, professional fruit packers, but the packing was a long business and done with minute care. Two purposely made hinged and paper-covered sloping boards for exhibiting the bunches were tied to the box containing the Grapes, with a letter of explanation for the Secretary. Our gardener took the box from Cottingham to Doncaster and handed it himself to the guard of the London train. My brother met the train at King's Cross and took the box in a taxi to Vincent Square. I do not think under the circumstances that it is possible for the Grapes to have been injured in transit, and a proof of their safe arrival is the "Card of Cultural Commendation," and my mother also had a letter from the Secretary of the Royal Horticultural Society expressing his interest and that of the Fruit Committee. My brother was not able to attend the show, but went in the evening to retrieve our property, and found only "the remains" of one bunch. One whole bunch and some of the other had apparently been stolen or eaten by the public during the show, and as your representative failed to find them, they seem to have been removed early in the afternoon. I do not know if this is a common occurrence with exhibits sent unattended, but it is not very encouraging to amateur exhibitors, who often, as in this case, may have taken an immense amount of trouble and incurred some expense in order to make an interesting display. I hope later to send some photographs of this little known Grape for publication, which will doubtless be a safer way of "exhibiting" them.—RUTH BICKERSTETH.

As far as we can ascertain these Grapes were never placed on public exhibition. They appear to have been left in the committee room. It is certainly desirable that all exhibits should be shewn to the public. We shall be interested to see the promised photographs.—ED.]

WILD FLOWERS AT COUNTRY SHOWS

I SEE in THE GARDEN for October 21, page 534, a paragraph signed "Horticus" recommending collections of wild flowers, including rare ones. Is it wise to encourage collecting anything rare? The country suffers from "collecting" rare birds, and although the collecting of rare flowers may possibly mean only the blossoms, in many cases it will probably mean getting the roots too. It is an interesting subject, and perhaps you could open discussion of it in your pages.—H. C. FORD.

ROSE PINK DELIGHT.

CAN you tell me anything about a Rose called Pink Delight? I was told it is a good pink single variety, but cannot trace it. If you know such a Rose, will you tell me its exact colouring and something of its habit of growth, etc.—H. G.

[The single Rose referred to would be Laxton's Pink Delight, which is a dwarf polyantha variety of wild rose colouring. The single flowers are of

points out several forms of hybrids, the colours of which vary from shades of red to yellow. It is worthy of note that they make excellent plants for bedding out in summer, and when so employed those which are pale in colour take on deeper tints in the open air. To see the *Diplacus* at its best under glass it should be planted in a border at the foot of a wall, where it makes vigorous growth in comparison to specimens pot-grown and, consequently, restricted at the roots.—CLAREMONT.

ABOUT SINGLE ROSES.

I DOUBT not that Mr. Jacob's article on page 553 would be read with considerable interest by lovers of single Roses. Notwithstanding the fact—as the writer has pointed out—that there is not one class in the National Society's schedule for single Roses, the day has gone when it is necessary to make any apology for their inclusion in the garden. If Roses are grown at all, then one cannot but admit their value for table decoration,

such, and the day will come when folk who grow them will pause as they stoop to cut the sprays on some June morning while the dew is upon them and say to themselves "How lovely! why ever didn't we grow them years ago." No! prejudice cannot stop single Roses. They are here, are coming still, and will continue to come, because the public have become quite enamoured of them.

Their delicate fragility, their charmingly subtle tints and the ease with which they can be grown are all reasons why they ought to be found in every garden where the Queen of Flowers holds court. The introduction of varieties like Irish Elegance, Irish Fireflame and Irish Afterglow did much to popularise them, and the worth of singles has been further enhanced since the sending out of Princess Mary, Mrs. C. E. Salmon and Isobel. These only need to be seen in bloom, surrounded in most instances with highly coloured foliage, to call forth admiration and a desire to have them. Wherever Roses are grown to-day for table decoration one can scarcely conceive an entire absence of singles, which are graceful and charming to a degree.—W. LINDERS LEA.

CHRYSANTHEMUMS AND "CURIOS."

IT was with some curiosity that I went to see the Chrysanthemum Show at Monte Carlo. Palms and Bananas do not agree somehow with one's idea of where to grow that useful winter flower. I must own, too, that the way this hardy flower withstands the heat and drought on this coast is an eloquent proof of the good gardening for which Monte Carlo is renowned. The "finish" of the enormous flowers alone shewed that a cooler climate would have suited them better, but the stocky growths and splendid foliage could not be surpassed anywhere. The hairy petalled Japanese varieties, however, were finer and more finished than any I can remember, and the bright pink of one unnamed variety was especially beautiful. They must enjoy more heat and light than other kinds. There were *no stands of cut bloom*, but instead enormous vases with sheaves of massive flowers arranged in many instances with coloured foliage of the Venetian Sumach, *Rhus Cotinus*. The effect was strikingly good, and might be copied elsewhere. Generally there were in each of these huge vases two varieties contrasting in size but matching in colour as much as possible. The effect struck me as being particularly artistic. Where do they find these huge vases, celadon green in colour? A dwarf could easily hide in them. They made one think of Ali Baba and the Forty Thieves. The comparative absence of white and yellow varieties was remarkable, and I noticed that the visitors gave all their admiration to the highly coloured blooms, though any shade of salmon pink was noted.

I was delighted to see a number of the new little dwarf Japanese single varieties that were shewn. They are decidedly attractive, though one loses all sense of their being Chrysanthemums (is that praise, I wonder?). They masquerade as *Asters*, *Cinerarias* or *Senecios*! One or two were silvery grey in colour, and I could have passed them as *Michaelmas Daisies*. One very distinct form mimicked a common Daisy to the life, and I could have sworn that a third was a *Senecio Jacobaea*! There are many shades of Havana or red-brown, but no really good yellow among the real dwarfs, those shewn being decidedly straggling and untidy in their growth. Open-air culture has much to say in this section, and I should doubt if they would be half so taking were they grown in pots under glass. All the same I should have a try.—E. H. WOODALL.

ROSE LAXTON'S PINK DELIGHT.

good size—much larger than the ordinary polyantha varieties—and the plant is a robust grower. The flowers are too irregular to appeal to a florist, but very attractive to more ordinary folk. The picture reproduced herewith gives a good idea of the habit and appearance of the plant. Quite a new variety, it is being sent out by Messrs. Laxton Brothers of Bedford.—En.]

DIPLACUS GLUTINOSUS.

THE interesting note on page 560 of THE GARDEN concerning *Diplacus glutinosus* being grown out of doors in mild localities calls to mind a specimen I saw some years since climbing over the front of a house in Cornwall, where it had evidently been long established. It is only in favoured districts, however, where severe winters are practically unknown that one can hope to succeed with it out of a house. In a greenhouse from which frost is excluded the *Diplacus* answers very well and is admirable for training over the back wall of a lean-to house or under the rafters. Small plants in pots were found in most establishments at one time, but of recent years they appear to have dropped out of favour. "T. W. B."

and for the home, and of all sections none is more beautiful or provides us with daintier specimens than do the single varieties. I can appreciate all that Mr. Jacob has advanced in their favour, and it seems to me that the sooner the executive of the National Society reviews the situation, and does what is right and proper by admitting the singles with full honours, the better it will be for the Society. It is, I venture respectfully to submit, only another case of history repeating itself. For a long time single Chrysanthemums were looked upon in disdainful fashion by many growers, and at first little encouragement was given by the N.C.S. to them; as a consequence not a few provincial societies, taking their cue from the N.C.S., with which they were affiliated, were disposed to give them the cold shoulder. I was on the executive of a provincial society and remember many a tussle we had before the walls of prejudice were broken down. The fact is that the eyes of many growers in those days suffered from the "big bloom beam," and they had no vision for the charm of the fragile and dainty singles. It is similar with single Roses. Objections may be taken to them in certain quarters, but their own beauty will overcome

THE ASPARAGUS BEETLE

The Life History and Control of a Serious Pest.

WITH the increasing popularity of Asparagus as a vegetable and the consequent probability of a number of new beds being made this autumn and planted next spring, it is necessary that more attention be paid to a pest which does a great amount of harm, especially to young beds and edible shoots.

The Asparagus beetle (*Crioceris asparagi*) is the only insect in this country which does an appreciable amount of damage to this crop. It is a well known fact that gardeners grumble if the "fern" is picked, as it weakens the roots, yet this beetle and its larva can be responsible for a complete defoliation of the bed in summer, while the marketable shoots are often so contaminated by the eggs and larvæ as to render them totally unfit for sale; also the success of the establishment of a new bed is seriously jeopardised if the beetle once gets firmly established. The distribution of this pest is at present localised, but its increase is reported each year, and unless stringent methods of control are immediately adopted the success of Asparagus growing in this country cannot in future be relied upon. At present the counties of Gloucester, Warwick, and Kent and the London district are most infested, but the pest is gradually spreading westward. Its presence has this year been reported from Somerset.

The adult beetle is graceful and slender and little less than a quarter of an inch long. The elytra are shiny dark blue and yellow or dirty white. There is a dark band running down the centre of the back with two lateral extensions towards the sides, giving a somewhat chequered appearance. The outer border is reddish, as is also the thorax, which latter has a number of faint dark markings forming a triangle, the base of which lies towards the insect's head. The distribution and relative amount of the blue and yellow varies considerably in different localities and in individual specimens. Some beetles appear to be marked with black and yellow, while on others it appears blue and white. On the same Asparagus bed even, specimens may be found which, as regards colour, differ considerably. The head is black, with fairly prominent eyes, and the long eleven-jointed antennæ are generally carried forward from the head. The identification of this beetle is, therefore, comparatively easy, even apart from its natural surroundings, the alternate colouring giving it a characteristic appearance.

The larvæ are of a dirty greenish grey colour, much wrinkled and always having a moist appearance. Apparently they moult three times, and when full fed are practically half an inch long. Six jointed legs are present, also a foot-like tubercle on each segment except the last, which bears a more distinct proleg. The head is black and possesses a biting mouth, while a drop of sticky black fluid may be excreted by the larvæ when disturbed—a peculiarity which is characteristic of most Chrysomilidæ. When full fed they generally go down to the soil to pupate, the parchment-like cocoon being hardened frothy saliva and is covered with particles of earth. Lintner, however, says "that instead of going down into the soil some larvæ merely conceal themselves beneath dead leaves and other material on the surface."

The large dark brown oval eggs are about one-twentieth of an inch long, and are found glued on to the fronds or heads of the Asparagus. The

larvæ hatch in about five to seven days and are full grown in from ten to thirteen days. The pupal stage lasts two to three weeks, but the beetles are matured three or four days before their appearance above ground. It will thus be seen that the life-cycle takes from four to seven weeks, depending on local climatic conditions. There are two or three broods a year, both adults and larvæ being frequently found up to October.

Adults and larvæ are harmful. Both continually feed from late May—when the edible shoots are attacked—throughout the summer into autumn, when, if present in large numbers, the green epidermis is gradually stripped from fronds and stem, giving the bed a whitish dead appearance. Also, as was mentioned before, the marketable value of the Asparagus is considerably reduced by the presence of eggs and grubs on the shoots,

A, Egg of the Asparagus Beetle (·18);
C, Larva (·6); D, Imago (·4); B,
Damaged shoot of Asparagus.

and their soiled appearance due to the black fluid which is excreted by the larvæ.

The control of the pest is greatly assisted by certain natural factors. In the first place, Fernald says "excessive heat appears to kill many of the grubs, and the alternation of severe cold with much warmer periods in the winter has a similar effect on hibernating adults." Hot weather and strong sunlight during summer cause many of the eggs to shrivel up, and the larvæ, if not killed outright, fail to reach maturity.

Predacious insects and birds help considerably in keeping down excessive numbers of the pest. Among the former may be mentioned the chalcid, *Tetrastichus asparagi*, which is a parasite on the beetle, since the adults eat some eggs and oviposit in others. The larvæ or "niggers" of the two-spot ladybird and the lacewing fly destroy the larva of the beetle.

There are various artificial methods at the disposal of the horticulturist. On small beds handpicking is perhaps the most effective, especially if it is resorted to before the beetle has become firmly established. On larger areas a very effective method of control, and one which is largely practised in America, is that of keeping the beds as clearly cut as possible, but leaving a few stalks at intervals to act as traps, on which the adult beetle lays her eggs, which can then be destroyed by cutting and

burning. This is continued throughout the early season, the traps being cut about every week.

The choice of several sprays is open, and this means of control has always been found very effective in practice. The best, perhaps, is an arsenate spray—arsenate of lead paste three to three and a half teaspoonfuls (level) to one gallon of water. In mixing the paste it is better to add some water to the paste and stir thoroughly before adding the rest of the water in order to get a uniform mixture. The Ministry of Agriculture in their Leaflet No. 47 advise, besides the above spray, a paraffin emulsion made by boiling ½ lb. of soft soap in one gallon of soft water and then adding 2 gallons of paraffin, churning till a thorough incorporation is obtained. This should be diluted with 15 to 20 gallons of soft water before use. In Germany a spray is used composed of 5 lb. of tobacco extract and 1 pint of lysol contained in 50 gallons of water, which is quite cheap and effective. A very simple and sure method of control, however, is the dusting of the bed every three or four days in the early morning with fresh air-slaked lime. HAROLD I. KINGSTON.

CHRYSANTHEMUMS

Notes on Cultivation.

THE work connected with the cultivation of Chrysanthemums during the past few seasons has reminded me, personally, of the game of cricket. One never can tell beforehand what is going to happen. There is a lot of uncertainty about seasons always, and as climatic conditions in general affect the growth, maturity and bud production of the plants, the cultivator's interest in them is always excited and never allowed to flag. Undoubtedly these plants are finding more and more favour with the public; their blossoms fill a big gap every autumn and early winter.

In the year 1921 buds of plants in the Japanese section, grown for the production of large blooms, were shewing as early as July 15. These buds were "taken" in many instances and the resultant flowers were excellent in every way. This year the buds of the same varieties shewed prominently during the first week in August, and the resultant flowers have been splendid, in some instances 25 per cent. better than those in 1921, but almost a fortnight later in development.

Such naturally late-flowering varieties as Victory, Louisa Pockett, Mrs. R. C. Pulling, Majestic, W. Rigby, Mrs. G. Drabble, Queen Mary and Princess Mary have this year been disappointing where the cuttings were inserted too late in the winter season; but autumn propagation of these and other late ones has resulted in plants of good strength, bearing blooms of great fulness and depth.

Beginners in the cultivation of Chrysanthemums would act wisely if, on reading these notes, they set about the work of propagation of all late sorts forthwith. Cuttings inserted during November and December take, as a rule, under cool conditions four or five weeks to form a few roots. Those inserted in January, three weeks, and others still later little more than a fortnight.

There is no better position for the midwinter batches of cuttings than one on the front greenhouse stage where the shallow propagating frame should be placed. It is only necessary to keep out frost and expel excessive moisture. There must not be any forcing temperature. If the blooms of Zonal Pelargoniums keep fresh and free from damp, the atmosphere will be ideal for the cuttings of Chrysanthemums. G. G.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Hot-beds.—Material for forming hot-beds should be thrown together and turned once or twice some little time before it is required. Where no straw litter is available for mixing with the leaves it is sometimes possible to make use of late scythings from pleasure grounds, etc., to assist in a little more rapid promotion of heat from the newly gathered leaves, but a bed made from leaves only is excellent for early Carrots, etc., so long as it is made quite firm and of several feet in depth.

Early Carrots.—To augment the supply of young roots which are being produced from autumn sowings outside, some seed should now be sown in frames. Place about roins, of light, rich soil upon a bed of leaves, etc., and sow the seed in drills 8ins. apart. For early frame work a variety like Early Market is suitable.

Horseradish.—If it is necessary to make a new plantation, deal with half the bed at a time, leaving the other portion to ensure a good supply while the newly planted roots are getting established. All the strong, thong-like roots of the lifted plants will make suitable material for planting again, having first cut them into lengths of 8ins. or roins. Plant the thongs in rows about 2oins. apart and a foot apart in the rows. The old crowns may be heeled in against a north wall to be drawn upon as required. Great care is necessary when doing away with an old bed to see that all the roots, never mind how small, are dug up or they will prove a nuisance to succeeding crops.

The Flower Garden.

Beds of Perennials, such as Phlox, Salvias and Asters should be lifted now if any division of the old plants is contemplated. Should the roots have been undisturbed for several years it will be found that their centres are getting weak and exhausted, so select the growths for replanting from the outside of the clumps. It is possible to leave such beds three years and still get first class results without again lifting and replanting, so the ground ought to be well dug and have some manure worked into it. Where it is necessary to have something in flower previous to such mentioned plants, there are several kinds which may be employed, Daffodils, Polyanthus and Forget-me-nots for example. An excellent plan is to introduce Liliums, both early and late.

Seedlings.—Antirrhinum seedlings and similar plants raised from an autumn sowing, if not already pricked out, should have attention. It is not a good plan to use a great depth of soil for transplanting the seedlings into, as they stand the climatic conditions of the next three months better in a shallow soil, whether it be in boxes, frames or on sheltered outside borders. Dampness must be carefully guarded against when the plants are grown in frames.

The Hardy Fruit Garden.

Protecting Figs.—This is advisable in cold districts during a severe spell of frost. It may be afforded in one of two ways, firstly by nailing mats or stout canvas over the trees without removing them from the wall, or by releasing the whole of the branches, afterwards tying them into convenient bundles, around which may be bound some bracken, fern or straw.

Planting Figs.—One of the most important items to bear in mind when planting fresh trees, or overhauling unsatisfactory ones, is to make sure that the drainage is ample and in proper order, for this is not only all important to a good finish to the fruits, but helps a great deal in cold districts to assist the trees through the winter, especially the more recently planted ones.

Mulberries.—An old well grown tree of this interesting fruit makes a picturesque effect in a garden and looks quite appropriate in a suitably chosen spot on a lawn. While thriving in most places without any special attention, it should be given the preference of a warm position, or a wall in very cold districts.

Nuts.—Cob Nuts and Filberts thrive in almost any ordinary garden soil, but they do best in one which is well drained. It is sometimes possible to make a plantation of them on a bank or on stony ground which cannot be made much use of otherwise. Bushes are the most convenient form as a rule for garden purposes and they should be planted about 5ft. apart on a bank, or 10ft. apart in a bed. Ten to sixteen growths make a good bush and pruning may be done on the spur

principle. All weak wood may be cut out and other strong growths present in addition to the selected branches may be cut hard back to one or two eyes. If standard trees are grown, prune fairly hard until a good head has been formed, when but little is required except thinning out of surplus branches.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Seakale.—Another batch of crowns of this useful vegetable should be placed in the mushroom-house with a view to forcing for use during January. Failing such quarters the roots may be planted in fairly deep boxes and placed beneath the staging of an ordinary greenhouse or stove, shading from light so that crisp and finely blanched growths may result. A thorough watering at the time of planting often suffices until the growths are ready for cutting.

Rhubarb.—A dish of Rhubarb is always welcomed early in the year, and may be had with the minimum of trouble provided a little heat is available. Place the roots underneath the stage in the greenhouse and pack firmly around with leaf-mould or old potting soil. Spray the crowns overhead occasionally and keep shaded in a similar manner to that recommended for Seakale. Failing the use of any indoor facilities, Rhubarb is easily forced in its permanent quarters by placing barrels over the stools and surrounding with a good width of stable manure and leaves.

Digging and Trenching will now occupy a good deal of time, and no opportunity should be lost in having this important work advanced whenever suitable weather prevails. It is a source of satisfaction to all gardeners when it is found possible to have the bulk of the heavy digging finished by the New Year, as this considerably facilitates the carrying out of any minor alterations in the garden during the early months of the year. Trenching should be practised in the kitchen garden as frequently as possible, breaking up the bottom spit well and enriching with good farmyard manure. By working the soil deeply air is admitted to a greater depth, thus increasing the depth of the fertile layer and enabling crops to produce fibrous roots at a greater depth than formerly. In addition the free ascent of moisture to the surface during summer is encouraged, due to the greater divisibility of the soil particles.

Fruit Under Glass.

Late Grapes.—These are much esteemed when it is found possible to keep them hanging in good condition until the end of the year, it being particularly pleasurable to be able to cut luscious bunches during the festive season. Particular care is necessary at any time, but more especially in a damp season like the present, both to prevent the berries from decaying on the one hand and the skins from shrivelling on the other. To avoid decay anything approaching a damp atmosphere must be guarded against, keeping both the paths and the surface of the border dry and maintaining a gentle heat in the pipes. This will ensure a free circulation of air and prevent stagnation in the atmosphere. Air should not be admitted if the outside conditions are humid, and only allowed when the weather is fine and bright. Shrivelling of the skins is generally blamed on to the overplentiful use of fire-heat, but this may be as readily caused by the borders being unduly dry. Once this occurs no amount of water will bring the berries back to a normal condition, but the evil may be checked by giving sufficient water to carry the Vines on until the time arrives for clearing off the crop. Should this contingency occur the border should afterwards be covered with a quantity of dry litter to counteract the moisture which will arise from the border.

The Flower Garden.

Replanting Herbaceous Borders.—During open weather the work of replanting the hardy plant border may be proceeded with. The soil should be dug at least two spits deep, working in plenty of well decomposed garden refuse in the bottom spit, as this is eminently suitable for lightening and enriching the lower strata of heavy soils. Old mortar rubbish or burnt refuse from the bonfire also renders stiff clayey soils less adhesive and assists in the quick production of new roots on the various plants. On light, gravelly

soils plenty of cow-manure should be added, also a liberal quantity of turfy loam where it can be conveniently procured. In planting use discretion in the colour arrangement and utilise the outer or younger portion of the roots, as these give by far the best results. Opinions differ regarding the size of the various groups, but clumps comprising from three to five plants in each prove quite adequate and effective in most mixed borders.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Goodham, Kilmarweck.

GREENHOUSE AND CONSERVATORY.

House Cleansing.—During the winter months an opportunity should be taken thoroughly to clean all plant houses. This is very important, as clean surroundings help considerably to ward off attacks of insect pests and fungoid diseases. The roof glass should be washed and all wall surfaces thoroughly scrubbed, and afterwards lime-washed with fresh lime, to which some flowers of sulphur should be added. It is important that the lime wash should be made fast so that it will not readily wash or rub off. Various substances are used for this purpose, such as oil, and also salt, but the only material that I know of which is really effective is skim milk, using about a quart to a bucketful of limewash. All standing material on the stages should be washed and where necessary replaced with fresh. All pipe-tracks should be examined and accumulated rubbish removed, so that the pipes are clear all round; this adds considerably to the efficiency of the heating system. Ashes from the stovehole should never be placed in contact with the pipes, as the sulphur compounds in them quickly corrode iron, especially when warmth and moisture are also present. In the London neighbourhood fogs are very troublesome, leaving such a deposit of soot that it is necessary to wash the glass. Here at Kew we often find it necessary to wash the smaller houses several times during the months of November and December.

Roof Climbers.—Now is a good time to take down summer-flowering roof climbers, thinning them out and partly pruning them back. In many cases it is wise to leave the final pruning until the turn of the year, because, if pruned right back too early there is a danger of their starting into growth during the dull days. The plants should be thoroughly cleaned before retying.

Winter-flowering Begonias have been very bright for some weeks now, and should be given the warmest position in the conservatory or greenhouse. Having been placed in a lower temperature than that in which they are grown, great care is required in watering, and they will stand much better if they are kept on the dry side. As regards colour the most distinct are Mrs. Heal, Elatior, Exquisite, Emita, Fascination and Optima. The last named is very effective for house decoration, its light, elegant habit and the pleasing shade of soft orange-scarlet in its flowers making it ideal under artificial light. As the plants pass out of flower they should be returned to a house with an intermediate temperature and plenty of stock should be kept, as one must expect a good many losses during their resting period. The Gloire de Lorraine section is as popular as ever and in the conservatory should be given the same treatment as advised for the foregoing varieties.

Camellias, whether grown in beds, borders, or pots, should not be neglected as regards watering, as dryness at the root is often the cause of bud dropping. Another cause of the same trouble is allowing the plants to carry too heavy a crop. Now is a good time to commence thinning the buds, which is best done in several operations. With the introduction of many beautiful single varieties, Camellias bid fair to regain some of their former popularity. Mrs. F. Sander, White Swan, Lady Clare, japonica grandiflora, magnolia-flora and Kimberley, are all beautiful single-flowered varieties. The most beautiful of them all is C. reticulata. This species is not happy for long under pot cultivation, and is best planted out in a well drained bed in the cool conservatory, using plenty of good, rough lumpy peat in the planting compost. Stocks of this fine Camellia are generally short, many cultivators failing to propagate it successfully. Although it can be rooted from cuttings, it is best increased by grating it on stocks of an easy rooting variety of C. japonica. The scion should consist of a piece of two year old shoot. This is where many propagators fail, as they use scions from one year old wood. They should be side grafted, and then placed in a close case in a cool house.

Royal Botanic Gardens, Kew.

J. COULTS.

OBITUARY

MR. GEORGE P. BERRY.

It is with deep regret that we record the death of Mr. George P. Berry, who for the last nine years has been Senior Instructor in the Horticultural Division of the Ministry of Agriculture. It was the good and great work he performed as Horticultural Lecturer to the Edinburgh and East of Scotland College of Agriculture that gained for him his important position with the Ministry of Agriculture, and it is interesting to remember that in each instance he was the first holder of the positions, while he was also the first practical horticulturist on the Ministry's staff. Mr. Berry was essentially a practitioner, and he, wisely, looked at all problems from the cultivator's standpoint. In a sense it was this that led to his comparatively early breakdown and death, for he was decidedly an outdoor man and the confinement of a deal of office work had an adverse effect on his health. He was the son of a well known Scottish gardener, and after serving his apprenticeship Mr. Berry gained valuable experience in various nursery and private gardens and, entering the Edinburgh Botanic Gardens, soon became foreman-in-charge of the glass-house department. From Edinburgh he went to Morpeth in charge of the experimental station of the Northumberland County Council at Cockle Park, and later was made lecturer in horticulture at the Armstrong College, Newcastle, from which appointment he came to the Ministry of Agriculture.

Mr. Berry brought with him a wide experience, human sympathy and, beneath a natural reserve, a geniality which made him respected and esteemed by everyone with whom he came into contact. He died on November 11, and his funeral at Hammersmith on the 16th was attended by many prominent horticulturists. The sympathy of a wide circle will go out to his widow and family.

Dwarf Polyantha Roses.—It sometimes happens that those who have a special fondness for Roses are least able to indulge their fancy owing to limited room. To all such some of the dwarf Polyantha Roses, which need little space, should appeal. For narrow borders and small beds there is no section which yields more dainty blossoms or has longer period of beauty than the Polyantha. Arranged in colour groups very beautiful effects may be brought about, and those who have been in the habit of relying on summer bedding plants for a display are finding out that among members of this minor section of the Queen of Flowers, some, in particular, are possessed of delightfully tinted blossoms and are very graceful withal. Once planting is done and they have become established Polyantha Roses need little in the way of pruning beyond removing the dead wood every spring. We are particularly drawn to sorts like Ellen Poulsen (pink), George Elgar (yellow), Katharine Zomet (white), Eugénie Lamesch (orange and yellow) and Mme. N. Levayasseur (bright crimson). These and others provide a wonderful display of blossoms over a much longer period than is usually supposed by those who have not made their acquaintance or who prefer the more perfect beauty of form of the Hybrid Teas.

The Snakeroot.—That very decorative late-flowering hardy perennial, *Cimicifuga cordifolia*, is a plant with many inexplicable and curious "common" names. For instance, we have heard it called both Bugbane and Bugwort as well as Snakeroot. These somewhat distasteful titles have not, however, proved any handicap to the plant itself. Its dainty creamy white

flowers have seen to that, while it must be valued for its easy culture and the readiness with which it grows in semi-shaded spots in the garden. One has no difficulty in propagating established plants, for nothing could be simpler than to lift and divide in the early spring months, just about the time that new growth is commencing. A point that should not be lost sight of when planting is the desirability of associating it with some other plant that retains its foliage well into the autumn. The *Cimicifuga* flowers in September and October, but before this its own broad, palmate leaves, that were so handsome in early summer, have become distinctly shabby, and it needs something else to form a background to its stems and flowers. These rise to a height of 2ft. to 2½ft., and terminate in spikes of creamy white brush-like flowers that are at their best in early September. Below the main spikes are a number of subsidiary ones which rapidly push on, and so the plant remains decorative for a very long season. A note should be made of it for a damp semi-shaded corner where September flowers are wanted, for in really large clumps the effect is splendid.

Wattle Hurdles—a Rural Industry.—We are informed that His Majesty King George has just sent a second order for wattle hurdles to Rural Industries, Limited, of Cheltenham. By

following the Royal example in ordering these useful hurdles readers will help to keep a good number of rural workers employed throughout the winter.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

VIOLETS ATTACKED (Mrs. R. R., N. Lanes).—The damage to the Violet leaves appears to be the work of slugs in the main, but there are some small galls, not however likely to be detrimental to the well-being of the plants, caused by a minute two-winged fly. The slugs should be trapped by placing lettuce or cabbage leaves on the ground near the plants or hollowed out halved potatoes, with the hollow beneath, and examining them daily.

THE GREENHOUSE.

ARUM FOLIAGE ATTACKED (C. T., York).—The Arum foliage is attacked by a species of *Phyllosticta* which is causing the spotting. The leaves should be sprayed with Bordeaux or Burgundy mixture.

KITCHEN GARDEN.

POTATOES ATTACKED (O. H.).—The Potatoes are attacked by corky scab, due to the fungus *Spongospora subterranea*. Do not use such tubers for planting next year.

MISCELLANEOUS.

- NAMES OF PLANTS.**—W. M., Lytham.—1, *Eucalyptus globulus*; 2, *Swainsonia galegifolia*; 3, *Isoloma hirsutum*.

BUILD ON A GOOD FOUNDATION.

In planting a garden or an orchard, whether large or small, for pleasure or for profit, it is important to lay a good foundation.

This means thorough preparation of the ground careful planting and, above all, healthy, reliable well-rooted trees, of good constitution, of the right sorts on the right stocks.

Inferior fruit cannot find a profitable market Good fruit can command one.

We specialise in fruit trees for Market Growers or Amateurs, and shall be pleased to give intending planters the benefit of over 40 years' experience in fruit growing.

Roses, Shrubs, Perennials and Alpines are equally well grown.

A SELECTION OF SAXIFRAGES

THE genus *Saxifraga* may truly be considered the backbone of the rock garden. There are species for sun and shade, for precipitous cliff and for the water's edge. The generality are easy enough for the veriest gardening tyro, yet there are species exacting enough to please the most ardent lover of "miffy" plants. The genus is divided into seventeen sections, each with distinguishing characteristics, but some of them are of scant interest to the average gardener. The principal ones for garden decoration are the Silver Saxifrage group—*Euaizoonia*, the tufted group—*Kabschia*, the mossy group—*Daetyloides*, and those of *oppositifolia* kindred—*Porphyrium*. The Robertsonia section is typified by London Pride (*S. umbrosa*), and the *Miscopetalum* group by *S. rotundifolia*. The *Engleria* section contains no really easy species. It resembles in some respects the *Euaizoonia* and *Kabschia* groups. To the group *Nephrophyllum* belongs the Fair Maids of France, *S. granulata*. The *Bergenia* section includes the rather coarse leathery-leaved *Megaseas*. The *Peltiphyllum* section, which contains that admirable waterside species, *S. peltata*, is nearly related to the last named.

There are vast numbers of *Euaizoonia* forms listed by nurserymen which, considering how easily the various species interbreed, is not surprising, but is, none the less, confusing, especially as practically identical forms are often sent out under widely differing names. A few species or sub-species are indispensable. These include the gorgeous, albeit monocarpic, *S. longifolia*, in very truth the Queen of Saxifrages. If the rosettes are to attain the huge dimensions of which they are capable and the spikes are to reach their maximum of length and fullest beauty of proportioning, the young plants must not be stunted at any stage of growth. Too often, purchased specimens are pot-bound when supplied and never properly overget the check. Home-saved seeds, sown immediately they are ripe in a very gritty compost with a good lime content, will germinate readily and, given ordinary care, grow freely, but

unless the plant was isolated from other Encrusted Saxifrages when in flower the plants will not be true to type, although scarcely less interesting on that account.

Saxifraga lingulata is another admirable Encrusted species with snowy plumes, and though smaller in spike and rosette than *S. longifolia*, quite perennial and exceedingly easy in any not too hot but open exposure between rocks and in liny compost. Smaller still, but perhaps most beautiful of all Encrusted Saxifrages is *S. lingulata lantoscana*, with mats of beautiful foliage and well

proportioned trusses of exquisitely pure white flowers. Both *lingulata* and *lantoscana* cross freely with *S. longifolia* to produce interesting and, especially in some cases, beautiful hybrids.

Saxifraga Cotyledon is a large rosetted species being second only to *S. longifolia* itself in that respect. It is an extraordinarily variable species and distinct forms have been given pseudo-specific names. Such are *icelandica* and *pyramidalis*. The former is just a gigantic form with spikes often actually longer than those of *S. longifolia* but less beautifully proportioned. *S. C. pyramidalis* has very distinct pyramidal plumes. Owing to the readiness with which it crosses with any other Encrusted Saxifrage, it is not by any means always sent out true to type.

Saxifraga Aizoon, after which the Encrusted section is named, is an exceedingly variable species, so variable that a typical form can hardly be said to exist. *S. Aizoon rosea* and *S. A. lutea* are two forms or, more probably, hybrids of garden origin, with heavily rose-spotted and pale yellow flowers respectively. Both have pretty and distinct rosettes and both are admirably tree flowering. *S. A. minor* is an interesting tiny form and *S. A. balcana* a rather "fat-looking" one with, apparently *Cotyledon* "blood." A packet of seed saved from one clump of a form of *S. Aizoon* growing in the open rockery will produce a bewildering variety of types. Large rosettes and small rosettes, round ones and starry ones, some looking as if outlined with hoar frost, some dark and dour and others, again, greenish yellow, all will be found, and a corresponding diversity in the shape and size of the flower spikes and the colouring of the individual blossoms will be noticed. This assumes, of course, that a fair collection of Encrusted species and forms is grown.

Saxifraga ciliensis is one of the most valuable for quickly forming stretches of silver filigree. Though apparently related to *S. lingulata* this is an inferior species as far as the flower is concerned. A smaller form in every way is properly called *S. c. minor*, but has been described as a distinct species under the name *S. Probyum* and is often, in nurseries, sold as *S. valdensis*. *S. c. major* is larger in all its parts than

THE QUEEN OF SAXIFRAGES, *SAXIFRAGA LONGIFOLIA*.

THE COMPARATIVELY THIN PLUME OF SAXIFRAGA LINGULATA VERA.

SILVERED STARS OF SAXIFRAGA PARADOXA.

SNOW WHITE PLUMES OF SAXIFRAGA LINGULATA LANTOSCANA.

the type is perhaps a hybrid with *S. lingulata*. *S. Hostii* is another rapidly spreading species with greenish-white flowers spotted pink. Its best form is called *Macnabiana*. In this variety the spotting is so heavy as to give the whole flower a pink appearance. *S. Hostii* is, however, a very variable, if not, on the whole, a very valuable species and many varieties are offered.

Saxifraga cartilaginea is a very distinct species with sharply pointed, rather aloe-like foliage and pinkish flowers. It is somewhat uncommon in gardens and, when seen, is usually known as *S. Kolenatiana*, which is indeed very closely related. *S. Kolenatiana major* is only a good form of the latter. It is often listed as *S. Sendtneri*.

S. paradoxa of gardens is a form of *S. crustata* or possibly a hybrid between that species and *S. Hostii*. It is remarkable for its long and narrow silver-edged foliage which gives the rosettes a very light and starry appearance. *S. crustata* itself is, by comparison, scarcely worth growing. To this (*Euaizoonia*) group belongs *S. mutata*. The black-green leaves are long (up to 2ms.) and wide even for their length. They are fringed with long viscid hairs but are entirely destitute of the silvery encrustation characteristic of the group as a whole. The flowers are coppery-yellow with spots of deeper colour, but are not showy. As might be expected from the foliage, the plant likes a cool, half-shady spot. It is monocarpic, but seeds freely and is easily raised.

The only Encrusted species which is at all difficult is *S. florulenta*, of which the habitat and peculiarities were so well described a few months ago by M. Henry Corréon (*THE GARDEN*, May 6, page 217).

From this one difficult Encrusted species one turns easily to the *Engleria* group, which have rosettes very similar in appearance to those of the *Euaizoonia* section, combined with red or yellow flowers. The red flowered species have red flower stems and bracts. The best known species is perhaps *S. Griesbachii*, but *S. Stribrnyi* is often seen. *SS. Frederici Augusti* and *porophylla* might almost be considered small forms of *S. Griesbachii*. They bear their flowers in spikes. *S. Stribrnyi* is a branching species and *S. media*, a Pyrenean, is somewhat similar, but smaller. The two yellow-flowered species, *S. Kotschyi* and *S. luteo-viridis* are more interesting than beautiful which remark might, perhaps, be applied to the *Engleria* section as a whole. The silvery rosettes are, of course, beautiful, but not more so than those of most of the Encrusted species. None of the *Engleria* species is, in the open country, really difficult in the limestone moraine if given the sharpest of drainage and freedom from drip and river mists. On low-lying ground, however, or near large towns, it is useless to plant any of them outdoors.

Before passing on to the exceedingly beautiful and interesting *Kabschia* species or the extremely useful and, in some cases, wonderfully beautiful "mosses," it may be well to write a few words on the culture of Encrusted Saxifrages from seed. The seeds are exceedingly minute and the tiny plantlets not only lime-loving, but exceedingly impatient of stagnant moisture. There are few gardens in which there is not an abundance of broken flower-pots. These potsherds should be crushed with a fairly heavy hammer and passed through $\frac{1}{4}$ in. sieve. About half the quantity of old weathered mortar-rubble and a little leaf mould, both passed through the $\frac{1}{4}$ in. sieve will, with a small quantity of coke dust complete the compost. Proper seed pans are better than pots and infinitely superior to seed trays for this particular purpose. Abundant drainage material—about half the panful—should be provided. The seeds should be mixed with a little fine silver sand previous to sowing. No covering with compost should be attempted, but the pans, having been dipped to the rim in a pail of water, should be covered with glass and brown paper and stood in a cold frame or unheated greenhouse. Most species germinate readily and fairly quickly though the seedlings are so tiny as to need close inspection lest they be overlooked. The pans must be uncovered immediately germination is evident.

(To be continued)

TREES AND SHRUBS FRUITING IN WINTER

All trees and shrubs which produce attractive fruits or berries are valuable. Those most worthy of attention, however, carry their fruits in the dull days of winter.

THE length of time that fruits and berries remain on the trees and shrubs varies very considerably from several causes. In the first place, it depends how soon the fruits reach maturity, become dead ripe and fall or are eaten by the birds. Some of the Thorns, for instance, we might liken to early and late varieties of Apples. A number drop their fruits as early as October, even if not interfered with by birds; others, *Cratægus Carrièrei* and *C. cordata*, for instance, usually hang on the trees in attractive beauty well into the New Year. Locality or environment also appears to play a no inconsiderable part in the keeping qualities (so to speak) of the fruits and berries.

The birds are, obviously, largely responsible for the length of time we are able to enjoy the many ornamental fruits in the garden. In some seasons when there is a shortage of food, possibly the ground frozen, the blackbirds and thrushes soon raid the bushes. Nor do we grudge our feathered friends their daily food. It is delightful to have them with us in the garden, and most interesting to watch them from day to day, always picking out the ripest fruits, commencing usually with the Mountain Ash (*Pyrus Aucuparia*). Fruits which ripen late they leave until last. Timid by nature, the birds seldom venture to feed on the berries growing on trees and shrubs in much-frequented places. This is why the masses of fruits remain so long conspicuously beautiful on *Pyraeantha Lalandei* growing against suburban houses, while away in the shrubbery borders the bushes are already alive with blackbirds and thrushes feasting on the fruits. In some seasons our Holly bushes are almost cleared of berries if we get a sharp spell of frost before Christmas. In the front garden here which abuts on the main road with a frequent service of buses, there are three Holly trees which the birds leave severely alone. I have seen these trees red with the previous year's berries when in flower.

Again, the birds are only copying human beings in their partiality for certain fruits. The ground may be covered beneath a tree with plenty of dead-ripe fruits, but another kind on a neighbouring tree is evidently more tasty, judging by the efforts of the birds swinging at the ends of the twigs.

Two very notable late-fruiting shrubs are Chinese species of the Firethorn, *Pyraeantha*. The more noteworthy is *P. angustifolia*, an evergreen shrub with bright orange-coloured berries,

Unfortunately, it is on the borderland of hardiness, and is best grown against a wall except in the favoured climate of the South and West. It resembles a *Cotoneaster* in some respects. In fact, when first introduced it was awarded a first-class certificate by the Royal Horticultural Society on November 29, 1904, as *Cotoneaster angustifolia*, a very excellent coloured plate of a spray appearing as a Supplement to *THE GARDEN* February 18, 1905. Attractive in autumn and early winter, it is in February and March that one appreciates most the beauty of the rich orange fruits.

Pyraeantha yunnanensis is of more recent

the foliage until late in the year and sometimes into January. The fruits are yellowish green. It is worthy of note that, though a native of Mexico, it is hardy in this country.

Cotoneasters are represented by two species in particular which are conspicuous at Christmas-tide and after, and to which birds do not appear partial. *C. rotundifolia* is a semi-evergreen often carrying its foliage and rich scarlet-red fruits until March. It forms a spreading bush 6ft. to 8ft. or more in height. Even better known is *C. frigidula*, remarkable alike for its wealth of red berries and the length of time they retain their beauty. Usually seen as a large wide-spreading bush, this *Cotoneaster* can be trained into a tree with a good thick-set trunk. The fruits often provide a remarkable contrast to the new soft green foliage in spring.

Several *Barberries* deserve attention as fruiting bushes in midwinter. Two of the most constant in the production of berries are *Berberis subcaulialata* and *B. Staphiana*. Both are Chinese species, forming wide-spreading bushes some 3ft. or more in height with gracefully arching branches laden with carmine-red fruits. The berries of *B. subcaulialata* are brighter in colour and have less "bloom" on them than those of *B. Staphiana*.

Celastrus articulatus is a vigorous climber belonging to the same Natural Order (*Celastraceæ*) as the Spindle Tree, and the capsule (fruit) opens in the same way to display the scarlet-seeded seeds. A specimen at Kew loosely clinging to branches of a Lime tree to a height of 30ft. or so is most attractive with quantities of brilliantly coloured fruits and seeds—a study in golden yellow and scarlet.

A shrub or small tree which the birds appear to leave severely alone is the Sea Buckthorn (*Hippophae rhamnoides*). It has clusters of orange berries lasting in beauty from autumn until February or March. Non-success with this valuable seaside or waterside plant is usually traceable to the fact that only one sex is grown. Male and female flowers are borne on separate trees, and both must be grown fairly close together to obtain fruits.

Pernettya mucronata is a spreading evergreen shrub 2ft. to 4ft. high, giving a wealth of brilliant fruits the size of peas and varying in colour from waxy white to blackish purple and including rose, lilac and mauve. *Pernettyas* are readily raised from seeds, but as only a portion of the seedlings produce really showy fruits, to reproduce these true increase should be by layering or by cuttings. To improve the type, however, recourse must obviously be had to raising and selecting seedlings. The *Pernettyas* usually retain the fruits until the early months of the new year.

The Snowberry (*Symphoricarpos racemosus*) is too often a neglected shrub. Grown in deeply trenched and well manured ground, it produces quantities of large white fruits weighing down the branches. The Siberian Crab (*Pyrus baccata*), the cultivated garden form, not the wild type, is the last of the Crabs to drop the cherry-like red fruits, often after Christmas.

Last, but far from least, though it is a British wild climber of the hedgerows, mention must be made of the Traveller's Joy or Old Man's Beard (*Clematis Vitalba*), decking all and sundry over which it can ramble with its abundant silky fruits.

A. O.

COLOURED FOLIAGE AND FRUITS OF *CRATÆGUS CARRIÈREI*.

introduction with rather small red fruits which are borne in profusion and attract attention long after those of *Lalandei* have disappeared. It appears to be quite as hardy as the better-known species for the open border and shrubbery, though we have not had a particularly hard winter during recent years to give it a severe test.

Three *Cratæguses* stand out from all the rest as late-fruiting kinds, the fact that they are correspondingly late in flowering giving them an additional value. *Cratægus cordata* (the Washington Thorn) carries its clusters of rather small orange scarlet berries to Christmas, or later if untouched by birds. *C. Carrièrei* is one of the handsomest of the family in flower and fruit. At present the bronze, crimson and gold foliage is conspicuous in the autumn sun with large fruits which often hang on the trees until February or March. *C. stipulosa* (*C. mexicana* of the Botanical Register) retains the fruit and much of

ABOUT NERINES

A small note to a great subject.—Some early history.—Which is the true sarrimensis?—Has there been more than one sarrimensis?—The coming of Bowdeni.—Catch of Exeter, and Barn.—Seedling raising.

THE history of the Nerine is a long and interesting one. It is a plant which has been known in the British Isles since the time of the Romans, and has since that time been a favourite with gardeners. The first mention of it in the English language is in the *Herbarium of the University of Oxford*, published in 1545, where it is described as *Nerine sarrimensis*. It is also mentioned in the *Herbarium of the University of Cambridge*, published in 1596, and in the *Herbarium of the University of Leyden*, published in 1680. It is mentioned in the *Herbarium of the University of Padua*, published in 1713, and in the *Herbarium of the University of Vienna*, published in 1753. It is mentioned in the *Herbarium of the University of Berlin*, published in 1793, and in the *Herbarium of the University of Göttingen*, published in 1800. It is mentioned in the *Herbarium of the University of Bonn*, published in 1804, and in the *Herbarium of the University of Munich*, published in 1808. It is mentioned in the *Herbarium of the University of Paris*, published in 1811, and in the *Herbarium of the University of Rome*, published in 1815. It is mentioned in the *Herbarium of the University of Florence*, published in 1819, and in the *Herbarium of the University of Pisa*, published in 1823. It is mentioned in the *Herbarium of the University of Padua*, published in 1827, and in the *Herbarium of the University of Turin*, published in 1831. It is mentioned in the *Herbarium of the University of Genoa*, published in 1835, and in the *Herbarium of the University of Naples*, published in 1839. It is mentioned in the *Herbarium of the University of Palermo*, published in 1843, and in the *Herbarium of the University of Catania*, published in 1847. It is mentioned in the *Herbarium of the University of Messina*, published in 1851, and in the *Herbarium of the University of Syracuse*, published in 1855. It is mentioned in the *Herbarium of the University of Catania*, published in 1859, and in the *Herbarium of the University of Palermo*, published in 1863. It is mentioned in the *Herbarium of the University of Catania*, published in 1867, and in the *Herbarium of the University of Palermo*, published in 1871. It is mentioned in the *Herbarium of the University of Catania*, published in 1875, and in the *Herbarium of the University of Palermo*, published in 1879. It is mentioned in the *Herbarium of the University of Catania*, published in 1883, and in the *Herbarium of the University of Palermo*, published in 1887. It is mentioned in the *Herbarium of the University of Catania*, published in 1891, and in the *Herbarium of the University of Palermo*, published in 1895. It is mentioned in the *Herbarium of the University of Catania*, published in 1899, and in the *Herbarium of the University of Palermo*, published in 1903. It is mentioned in the *Herbarium of the University of Catania*, published in 1907, and in the *Herbarium of the University of Palermo*, published in 1911. It is mentioned in the *Herbarium of the University of Catania*, published in 1915, and in the *Herbarium of the University of Palermo*, published in 1919. It is mentioned in the *Herbarium of the University of Catania*, published in 1923, and in the *Herbarium of the University of Palermo*, published in 1927.

... the fact that when it comes in the second edition of the *Herbarium of the University of Oxford*, it is described as *Nerine sarrimensis*. It is also mentioned in the *Herbarium of the University of Cambridge*, published in 1596, and in the *Herbarium of the University of Leyden*, published in 1680. It is mentioned in the *Herbarium of the University of Catania*, published in 1923, and in the *Herbarium of the University of Palermo*, published in 1927.

It certainly comes with what some years ago was sent to us as the true variety. We are, however, to the interesting question: What is the true variety? Guernsey Lily like that for centuries used to be grown in that island and to be sent over to England every July or August in great quantities, to fill in one's, so I imagine, and then to be thrown away! Can it have been the same sarrimensis which a well known Guernsey man described in a letter to me in 1914 as behaving "in such a hopeless manner that it has ruined the whole family"? Can it have been the old variety which veterans like my friend Mr. William Mauger know so well and which he has told me was practically snuffed out by a frost of unprecedented severity in 1875, for none was then grown under glass? The advent of the almost hardy variety Bowdeni has introduced two new factors which before were unknown. First, increased hardiness! Dear old Mr. Peter Veitch has gone for this, and his name are now able to supply hybrids between Bowdeni and other varieties, which in the favoured climates of Devonshire and Cornwall are able to take care of themselves out of doors all the year through. Bowdeni itself has lived here at White-well for three winters unharmed at the foot of a warm south wall, but it is so late to come into bloom, that we always get bad weather before the umbels are anything like fully developed. The second factor is size. The result of a cross between Bowdeni and curvifolia (Fothergillii), which suddenly appeared in the R.H.S. Hall in the autumn of 1912, literally took one's breath away. It was one of those pleasant shocks which lovers of flowers get from time to time, as when, in the past Mrs. Berkeley of Spetchley electrified us with her

THE NEW STARLET NERINE HIS MAJESTY.

THE NEW STARLET NERINE HIS MAJESTY.

SOME STONECROPS IN AUTUMN

Hippastrums of Sir George Hilliard and Hippastrums of Mrs. R. O. Barkhouse with the celebrated Daffodils. Mr. James Rose of Oxford may now be added to the select company of those who have given us these unexpected plant surprises. His Flora measured eight feet in diameter, in which were thirteen flowers.

As Messrs Robert Veitch and Sons of Exeter specialise in Brompton and Brompton hybrids, so do Messrs Barr and Sons in the northward varieties which everywhere need some protection, although in favoured places it may only be a frost-proof cold frame. Their Nerine list contains nearly 100 varieties, so there is plenty of choice. This last autumn they received two awards of merit for novelties, viz. "Glitter and His Majesty." It is very little use making a selection, because what I may call the stock varieties, known by name, are not many. There is, of course, the old Fothergillii major, tall, tree-flowering, one of my pots with three bulbs in it had four spikes of bloom this autumn, and of a lovely soft red colour. There are Lady Mary Shelley, a most satisfactory pure pink; sarcocolla, a most pretty soft orange red, not very large or tall, but one of the most free-flowering; Meadowbankii, rich deep scarlet; Epio, a rose; Rothschild, a fine salmon red; and Lady Bromley, mauve and cerise.

This is about the time to think of sowing seed. If a person is attempting it for the first time, he will very likely do what I did, keep waiting and waiting for it to look as if it was ripe. I should be waiting still if a friend had not told me that it never looks ripe, but remains all the time a vivid green. As soon as it comes off with a touch it is ready to be gathered. I usually keep it in an open bag for ten days or a fortnight and then sow it in pans. It is well to give plenty of room, for the seedlings may remain where they are sown for three years. Then they should be transferred into 3 1/2 in. pots and left there until they bloom. This takes place in the fourth, fifth or sixth year, or it may take longer still. If, however, seed is saved from varieties which have proved themselves to be good bloomers and none others, it is probable that the seedlings will flower at an earlier period than would otherwise be the case. As an example: from seed sown in December, 1917, I have had plants which have just bloomed. The gradual attainment of a free-flowering race has been the chief object of Mr. Elwes's work. He has effected an enormous improvement, but there is much still to be done in this respect, therefore there is room for more workers on the same lines. The first period of waiting is long, but once that is past, if seeds are sown every year or even every other year, there will be an annual display from plants which have never bloomed before. Good top spit loam lightened with silver sand and some old rotten manure makes an ideal soil. When the foliage is fully developed feeding with alternate doses of weak soot water and weak "Clay's" or some similar manure is necessary. All water must be withheld when the foliage has turned yellow, and then all summer long they must have as long and as good a baking as possible. Let them have all the sun there is. Whatever shortcomings there may be in Nerines, they have one great compensation. They might be cats, they have so many lives. It is surprising what poor conditions they will stand, but naturally, as we treat them, so shall we reap.

J. J. J. J.

Since the above article came to hand the sad news has been received of Mr. H. J. Elwes's death. Mr. J. J.'s appreciative words with regard to the progress of the work of this great gardener have therefore become in a some degree a tribute to his memory.—E. J.

THE autumn stonecrops are a most interesting group, and one which is well worth the attention of the gardener. They are a most interesting group, and one which is well worth the attention of the gardener. They are a most interesting group, and one which is well worth the attention of the gardener.

Looking at these in S. Sedum, the most common, which is a most interesting group, and one which is well worth the attention of the gardener. They are a most interesting group, and one which is well worth the attention of the gardener. They are a most interesting group, and one which is well worth the attention of the gardener.

The less hardy S. Boissierii has been in flower here right up to mid-November in a sheltered corner, the silvery, pink-tipped flowers nearly half an inch across, being very bright and hearty. Another late bloomer is S. rotundum, with spatulate leaves distinctly notched at the apex and white flowers, but whether this Mexican will put up with our winters in the open remains to be proved. Quite the reverse of the genus now in flower, however, is an almost pure white form of S. spurius which has apparently been kept back by being planted in a rather shady, damp place. The inflorescence of this specimen is unusually large, both the individual flowers and the spikes, and the foliage has remained a rich, dusky green without a tinge of red. The leaves of other plants, notably of S. spurius var. splendens, are a bright crimson, these being in full exposure and a dry soil.

At this season the very beautiful little S. brevifolium var. Potted assumes its most vivid tints, the grey mealiness becoming almost an electric blue which is set off by the warm red at the leaf tips. This is a most delightful and easy plant, if no more than three or four inches high, and one that will readily establish itself in the crevices of heavy rocks.

Both S. rotundum and S. Nevi have been a glowing crimson for many weeks, a colour which perhaps they might not so readily acquire were they accorded the moister and more sheltered conditions which they evidently enjoy. They prosper very well, however, with ordinary treatment, so long as the soil is not too dry in summer, and few species are more charming when their mats of foliage are covered with the branching heads of silvery white flowers at midsummer.

Another species which prefers an even damper situation than the above is the splendid S. pulchellum, perhaps the finest hardy Sedum in cultivation. Not only are the large, dew-like, recurved inflorescences in a bright clear pink strikingly handsome but, throughout the autumn, the linear leaves which crowd the semiprostrate growths are an intensely vivid blood crimson.

Of S. spathulifolium there are several forms, as beautiful as they are confusing. Though good at all seasons, the fine yellow flowers being large and attractive, the various members of this species are seldom quite so fascinating as when the rosettes assume the mealy crests, soft dove colours, and purples of autumn and winter. From the small-leaved, glaucous and often red-tipped form, probably the typical plant, to the fat and the var. purpureum majus, or var. "Wm. Paulsen," as it is sometimes listed, which never recedes at the tips, remaining a full plum purple with a mealy bloom, there are a number of intermediate sizes and colours. They are all of hardy and easy maintenance, and maintain their beauty throughout the winter.

THE autumn stonecrops are a most interesting group, and one which is well worth the attention of the gardener. They are a most interesting group, and one which is well worth the attention of the gardener. They are a most interesting group, and one which is well worth the attention of the gardener.

THE GARDEN FRAME

How to make the best use of it during the dull days of winter.

THERE are few lovers of gardens who do not possess a frame either cold or heated. The latter is generally filled with plants, cuttings or bulbs during the winter months and really good use is made of it, but the cold frame—the kind I have heard of and seen—often neglected, mainly through ignorance as to the right way to manage it. It is certainly a great pity to allow a cold frame to remain empty or in any way neglected during the winter months. The frame is a great asset to the gardener, whether the latter resides in town, suburb or far country. Yet, I think, in town and suburb the frame is of more value than in the country, because it is a means of protecting many kinds of plants from the effects of chemicals and gases which would otherwise prove harmful. The lover of alpine and rockery plants often possesses numbers of small specimens which are in need of nursing for a time; the cold frame is ideal for such. I know from personal experience that the suckers and roots of border Chrysanthemums suffer from severe frosts when left quite unprotected. Planted in the cold frame the roots will be quite safe and propagated from them may be turned in at any convenient time. Bulbous rooted cuttings of Narcissus would be quite safe in the cold frame till March, or even very late planting in a cold border might prove successful. The same remarks apply to various members of winter plants, the best examples being the various Cyclades and quite a number of the cold frame is especially suitable for wintering about. Cuttings of Calluna are safe in a cold frame in cold frames and in an ordinary winter bed the plants and of the same kind, but I believe they may suffer if they are not covered there. Very little watering is needed, but plenty of fresh air is essential when the days

are mild or sunny, without frost. Bulbs, of various kinds, do remarkably well in a cold frame if placed there for several days, or even weeks, after being taken from the bed of sand or ashes. Then, as the New Year comes, hundreds of seedlings or young plants of Lettices, Cauliflowers, Onions or Leeks may be raised in the small garden frame,

thus ensuring early crops of these in the open border.

Always ventilate so that air may circulate freely among the plants without causing cold draughts. Remove all decaying leaves weekly. When frosts come, cover the lights with mats, straw, short litter, bracken fern fronds, etc., and

in prolonged spells of frost pack short litter against the sides of the frame as well as on the top. If the cultivator feels sure that the plants have been frozen, leave the covering material on till a natural thaw is complete. The plants are then much less likely to suffer harm than if prematurely exposed to light and air. G.

CARNATIONS AND CHRYSANTHEMUMS AT VINCENT SQUARE

THERE was to have been the Winter Show of the British Carnation Society at the R.H.S. Hall, Westminster, on November 20, so three of the principal Carnation nurserymen had arranged handsome collections for the R.H.S. meeting of the previous day, intending that their groups should

stand over. For some reason the Carnation Show was abandoned. Nevertheless these collections gave great pleasure to visitors. In Messrs. Allwood's interesting selection of the comparatively new Perpetual-flowering Border varieties, Sussex Beauty, Sussex Bizarre and Sussex Crimson were all of considerable value. The blossoms shown

were from plants lifted from the open border. Among the ordinary type of Perpetuals, the vivid colour of Edward Allwood was very prominent. This bright colour was also present in a collection arranged by Mr. C. Engelmann, who had large vases of Thor in intense colour, and the crimson Topsy, which received an award. Laddie, a new pale salmon-pink, was also of merit.

The large-flowered White Pearl has been shown in such quantities throughout the year, by Messrs. Stuart Low and Co., as to disabuse those who thought it might be a shy blooming variety. In Boadicea they have a new Perpetual Malmaison of quite uncommon rosy cerise colouring. It is a very decorative Carnation. Several vases of their new Eileen Low, grouped in the centre, were singularly effective.

A warm greenhouse plant not often seen nowadays is *Plumbago rosea*, but Mrs. F. B. Summers, Alton, Hants, sent a goodly group of plants which instanced first-rate cultivation. The graceful racemes of warm rosy flowers were greatly admired.

A long stretch of tabling was filled by Messrs. Blackmore & Langdon with greenhouse Cyclamens bearing plenty of good blooms. Mr. J. J. Kettle had a great many bunches of the Violets he grows so well in the pure air of Dorset, and Messrs. F. H. Chapman, Limited, showed seedling Nerines. For the most part they were quite ordinary, but a salmon pink seedling of compact type with waved segments was very good.

Chrysanthemums occupied a considerable proportion of space. The largest group was set up by Messrs. Keith Luxford and Co., and their large-flowered Japanese varieties were of considerable merit. There were also many vases of smaller Decorative blooms, while the Singles possessed great charm. Baby Jack, a small-flowered Single, was shown in graceful sprays of good yellow colour. Catriona, Molly Godfrey, Mensa and Flossy were also of great charm. Mr. Norman Davis had a large vase of his new Pink Favourite and also one of Cream Favourite, which is a good companion variety. Messrs. J. Godfrey and Son had some vases of Singles and also showed Golden Dot, a pretty little Pompon Chrysanthemum.

The exhibit of winter-flowering Sweet Peas did not attract as much attention as might have been expected when one considers the enormous popularity of the Sweet Pea. These winter varieties are much smaller than the summer sorts, but many of them are quite dainty and are eminently suitable for table decoration. The Rolvenden Nurseries showed Mrs. Kerr, of salmon pink shading; Flamingo, pink shades; Princess, mauve; and White Star.

NEW AND RARE PLANTS.

Carnation Topsy.—We have on various occasions during the year remarked on the merits of this rich crimson Carnation. The well formed blooms are among the largest of the Perpetual-flowering varieties; it is deliciously fragrant, even in winter

MUCH IN THE WAY OF THE OLD W. H. LINCOLN, CHRYSANTHEMUM GOLDEN BUTTERFLY.

AN ADMIRABLE YELLOW SINGLE SPRAY CHRYSANTHEMUM, BABY JACK.

and is said to be very free-flowering. Award of merit to Mr. C. Engelmann.

Chrysanthemum Dr. J. M. Inglis.—The chief value of this large flowered Japanese variety lies in its uncommon colour, which is described as purple amaranth with silvery reverse. It has large broad petals, but seems to lack stamina and would soon droop. When at its best it is exceedingly attractive and will no doubt be valued by exhibitors. Award of merit to Messrs. Keith Luxford and Co.

Chrysanthemum Golden Butterfly.—This is a very useful decorative variety which bears flowers strongly reminiscent of W. H. Lincoln, the late-flowering yellow of thirty years or so ago. It is rather a fuller bloom, the stout florets are erect and of deep yellow colour. A plant was also on view and this was dwarf and free blooming. Award of merit to Messrs. Scott and Wickham.

Chrysanthemum Mrs. A. Robertson.—This is a broad petalled pinkish mauve single variety of very good type and rather larger than Mensa. Award of merit to Mr. Norman Davis.

Chrysanthemum Pink Favourite.—An excellent market variety that should also be of great value for home use. As shewn, the blooms were of slightly irregular incurved habit, but this was said by the raiser to be due to the necessity for subjecting the plants to rather too great a heat in order to bring them into flower by the time of the meeting. It is a sport from the valuable market variety White Favourite. Award of merit to Mr. Norman Davis.

Chrysanthemum Robert Collins.—A medium sized single of graceful form, the tip of the petals recurring evenly. It is of bright orange buff colouring. Award of merit to Mr. G. Carpenter.

Cypripedium Godefroyæ Splendid.—A very good example of the Dreadnought or Bulldog Lady's Slipper. It is a rounded, slightly cupped flower spotted with maroon and tipped with white. The pouch is nearly pure white. Award of merit to Messrs. Sander and Co.

Odontoglossum Armstrongii Aureole.—A most beautiful variety. The plant bore only one flower which was of perfect form and uncommon canary yellow colour tipped with white. The crest was of a deeper shade of yellow. First class certificate to Messrs. Armstrong and Brown.

Odontoglossum eximillus Tintoretto.—This was a spike of well formed flowers of bright rosy maroon colour, very lightly margined with white as narrow as the line of colour on a light-edged Picotee. Award of merit to Mr. J. J. Bolton.

Odontoglossum Magnificent.—A beautifully formed flower of chocolate colour, tipped with white and with a rosy maroon lip. Award of merit to Messrs. Sander and Co.

BONFIRE ASH OR HUMUS?

THE valley where I live, and the outskirts of the principal town, have been hazy with the smoke of many bonfires for weeks past. The weather has been dry, there has been rubbish to rake up and every gardener, from the plot holder to the man who sweeps the squire's avenue, has been busy

charged with humus that they do not need any addition, but porous, thin and light land, and that which is cold and stiff are alike vastly improved by the incorporation of vegetable substance, while sandy land is often totally unable to support the life of the majority of plants without it.

It is doubtless true that the bonfire is the most efficient receptacle for any rubbish which may contain disease spores, noxious weeds which resist decay, or insect pests. Woody material is also best put out of the way by burning. But where there is one bonfire made with the object of carrying out some definite object of that kind, there are a dozen made just to consume what is generally and thoughtlessly termed "rubbish," but which is actually nothing of the kind.

Now in regard to making the best use of our autumn leaves, weeds and other garden clearings—anything that will decay—each one must act in accordance with his circumstances. For general garden use, such as top-dressing borders and shrubs, and for supplementing the little organic manure I am able to get for vegetable growing and, indeed, for practically the whole round of gardening on a light and gritty soil, I work on these lines: All the vegetable refuse is taken as collected (and this is practically always going on), and placed in shallow pits or heaps in convenient corners. These sometimes get the addition of a little road soil. No lime is used on the heaps for two reasons, one being that the compost may be eventually needed for plants which dislike lime and the other that lime has a tendency to destroy humus and thereby defeat one's whole object. Salt is used instead and it will be found that an occasional sprinkling will both assist the decomposition of and sweeten the contents of the heap. When available, fresh soot is dusted over the compost pile and this also accelerates decay, it enriches the mixture, pests dislike it and it imparts a dark colour to the compost which has certain advantages on light land.

During winter or, indeed, at any time that may be convenient, the heaps are turned over and, as soon as one is large enough, no fresh rubbish is added to it, a new one being started instead. Working on that principle we always have at hand at least one fully matured heap (about a year old) of compost which is rich in humus and sufficiently charged with fertilising elements for general purposes. As a matter of fact we have used such material exclusively for years for a wide variety of plants in woodland and border, for heath bank, Ferns, Rhododendrons, wall shrubs and others with the fullest satisfaction, only adding to it a little old animal manure for such things as need more liberal feeding—and this on a particularly hungry soil.

It is sometimes contended that vegetable compost of this kind is liable to bring weeds and other undesirables where they are not wanted. That has not been our experience. We have, indeed, never had any trouble of that kind which could be traced to such a source. A vegetable mixture, made in the manner I have described, is infinitely "cleaner" than most farm and stable manures, it costs nothing, its use is the practice of garden economies in the truest sense and the application of a principle which is one of the most fundamental of nature's laws.

A. F. J.

FORTHCOMING EVENTS.

December 11. United Horticultural Benefit and Provident Society's Meeting.

December 12. Royal Horticultural Society's Fortnightly Meeting.

DEEP CRIMSON PERPETUAL CARNATION TOPSY.

firing the results of his labours. That these bonfires are a mistake all who have stopped to think must admit, for it is an odd fact that the very gardeners who are keenest to reduce a cartload of vegetable refuse to ashes are usually the very people who are for ever regretting the growing shortage of organic manure. They know that most lands must have humus of some kind applied to them if they are to continue fruitful and if artificial fertilisers are to be used continuously with safety and economy, yet they annually make these burnt offerings to the god of custom and thus doing destroy the very material which might mean so much to them.

Properly used the great bulk of this vegetable refuse might, with the aid of suitable "artificial," prove a perfectly efficient substitute for horse manure in allotment or kitchen garden; but apart from that, regarded only as a means of restoring to the land some of that humus which is ever being used up under cultivation, such vegetable matter might be of inestimable value to most of us. There may be some soils already so

THE EXPEDIENCY OF GRAFTING

As applied more particularly to Clematises.

THE controversy as to the comparative merits of own-root Clematises and those grafted on stocks of the Traveller's Joy, *Clematis Vitalba*, is again brought to the fore by a letter in our Correspondence column from Mr. A. G. Jackman. This may therefore be considered an opportune moment for the Editor to sort out the facts bearing on the value of grafting on the one hand and its abuse on the other. There is nothing which can be written which will be new to most readers. It is hoped, however, that the ordered presentation of the facts may be helpful to many who have little time to spare in sifting evidence and making deductions about matters horticultural. First, let it be said that there is abundant proof that hybrid Clematises root freely from layers and grow strongly upon their own roots. In this respect they differ materially from certain other shrubs—Roses, for instance. Many garden varieties of Rose, which are quite satisfactory when budded upon the briar, are absolute failures on their own roots.

There are obviously drawbacks from the nurseryman's point of view to propagation solely by layers, so that it is worth investigating whether grafting is in fact harmful, and responsible for the sudden collapse of plants with which all gardeners are but too familiar. That *Clematis Vitalba* is a species very distantly related to the large-flowered *Jackmani* and *lanuginosa* hybrids is self evident, but it is only fair to point out that such distant relationship is by no means proof of incompatibility. The relationship between the Dog Rose, *Rosa canina*, and *Rosa indica* is, in all probability, equally distant, and the latter species owns the larger share of the parentage of many of the very best and newest garden Roses. *Rosa Wichuraiana* has equally little affinity with the Dog Briar, yet the *Wichuraiana* hybrids when budded upon the wild Rose stock flourish amazingly and have an exceedingly long, useful life. So great is the sympathy which seems to exist between *Rosa Albéric Barbier*, for instance, and the Dog Rose stock that the stems of standards will often swell exceedingly when the scion gets into full growth. Stems 3 ins. or 4 ins. thick are not uncommon in such circumstances. Such stems are never seen on the Wild Briar growing free.

There is no doubt whatever that the grafting of Cedars on Larch stocks, to take but one example, is thoroughly unsatisfactory, but when all is said the Traveller's Joy is a Clematis!

It would seem, therefore, that we are not likely to be able to decide the fitness of the particular method of propagation employed for the Clematis by analogy with other families of plants. Mr. Jackman in his letter recommends to plant grafted plants deep enough to allow the plant to establish itself upon its own roots. There is no doubt whatever that this should be done if only to allow

the plant to break again from the base when the original shoot gets damaged or becomes outworn. It has been suggested that even if this be done the roots of the original stock will still prove detrimental to the plant and may cause it suddenly to fail altogether.

A plant of *Clematis Jackmani* which this past season reached a height of 18ft., if not 20ft., and bore many hundreds of blossoms, is growing in very poor hungry soil with its growth for several

CLEMATIS NELLIE MOSER.

feet above ground-level in almost dense shade. It has had no manure since it was planted about twenty years ago, and has had no attention of any kind (even pruning) since 1914! This plant was grafted in the usual way, and planted so that the junction of stock and scion was covered.

This is only one illustration of many which might be given, all tending to prove that grafted plants are not necessarily short-lived. Nor, as Mr. Jackman very pertinently points out, is dying-back confined to grafted plants. There is at least a reasonable probability that this dying-back

or sleeping sickness may be due to a definite disease. If such were the case, one would expect plants grown under natural conditions to possess more resistance than those in less favoured circumstances. Granted that the Clematis is a woodland plant and likes a cool root-run, the expectation is fully borne out. It is comparatively seldom that plants, given favourable conditions, fail, whereas on a pergola, where sunlight strikes right down to the roots of the plant, "dying back" is common.

To sum up, own-root Clematises are undoubtedly satisfactory if planted in suitable positions, but there seems to be no real weight of evidence to show that grafted plants are not almost, if not quite, as likely to succeed.

LAWNS IN WINTER-TIME

A REALLY well kept lawn, especially during the summer months, goes far towards making any garden, large or small, a pleasure to its owner. Exceptionally dry summers spoil the appearance of most lawns unless, indeed, they are situated in low-lying districts or near large ponds or rivers. Fortunately, we have not often to contend with parching heat and a long succession of rainless days in this country.

The Small and Medium-Sized Lawn.—Such may be very thoroughly dealt with, and there is no time better than the early winter months for undertaking all work of renovation. A lawn, even if well made, with fairly good soil to a reasonable depth beneath, will become exhausted in the course of a few years unless some feeding material is put on at the right time. The regular removal of the short grass in the summer exposes the roots to the fierce rays of the sun, and after a time the grass shews signs of failing. There is nothing which can be done at that season except to remove the grass box from the mower, thus allowing the grass as cut to spread itself on the lawn. If this be done occasionally the roots will benefit. In early winter, however, we can dig up the roots of coarse weeds and Daisies and apply a top-dressing. Before any surface mulch is put on, grass and soil should be vigorously raked with a sharp-toothed iron rake. Mix together old rotted manure one-third and sand, rather retentive loam two-thirds; if fairly dry at the time, there will be no difficulty in thoroughly breaking up both loam and manure. In the case of poor lawns, two barrow-loads per square rod of ground may be applied; for an ordinary lawn, not badly exhausted, one barrow-load will suffice. Once a week the material should be brushed in but not rolled. At the end of February or not later than the middle of March 1lb. of bone-meal per square rod should be applied. Another brushing should take place immediately, followed by a thorough rolling, and rolling ought to be continued once a week till the first mowing is done. Never roll when the lawn is really wet. Bone-meal will be effective for quite six months.

The Large Lawn. To treat a lawn of several acres in extent similarly to one of several rods would entail much labour and expense. I should not hesitate to make use of a very light "Parmenter" grass harrow in place of the rake if the lawn was at all unsatisfactory. It is wonderful how much a lawn will stand in the way of pulling about and be benefited instead of harmed. Road grit, ordinary soil and a small proportion of manure, mixed, spread broadcast and then worked in with the aid of a chain harrow will prove a very effective dressing, cheap in itself and not expensive to apply in the way suggested. Of course, bone-meal may also be used if necessary. G. G.

FERNS FOR BASKET CULTURE

OF plants that add to the beauty of the greenhouse and conservatory when grown in baskets and suspended from the roof, there are few that excel the Ferns, particularly if the longest possible period of active service has to be borne in mind. It is true that they do not add brilliant colour—that is upon the staging beneath—but one and all possess the indispensable charms of beauty and grace of form in no mean degree. One can be very sure that a house where Fern baskets are plentifully in evidence will present an attractive appearance throughout the year.

The best type of basket for the purpose in view is the common galvanised wire one, thickly lined out with fresh green moss, and it should be noted that it is by far the best way to

the baskets are really large, with fine specimens growing in them, the weight is considerable and heavy labour is involved in taking them down from their hooks, immersing and replacing. When basketed as described, so that the plant stands at the centre of a saucer-shaped depression, it is an easy matter to mount the steps with a can of water in hand, fill them up once or twice with the certain knowledge that the job has been efficiently done. A point, which is sometimes overlooked in choosing the position to hang basket Ferns, is the proximity of ventilators with their ill-effects in the drying air currents that they admit. This evil is most pronounced in summer, a season, too, when it is most likely to be overlooked: for in winter and spring, even if the ventilators are open the atmosphere is moister and much less harm is

A NICE BASKET OF DAVALLIA DISSECTA.

re-make these annually each March. Constant watering is essential to provide sufficient moisture where hung just beneath the glass; the body of soil is comparatively small, it has a considerable quantity of growth to support and—by the end of twelve months—has become almost exhausted. Re-make them therefore every spring, using fresh moss and fresh soil and so give your fern baskets the best possible chance. Compost varies somewhat with the variety that is being grown, but, in all cases, I have found that the addition of a fair proportion of peat is a great advantage. This is very absorbent and capable of taking up a large quantity of water which it retains in suspension and yet does not unduly saturate the roots. When filling in the soil in such baskets, a point should be made of doing this in such a way that it slopes down from the edge slightly towards the centre, so that, when water is poured in, it will penetrate the ball and go through to the roots and not pour off over the edge.

One of the worst methods of basketing is that where the Fern stands upon a cone of soil for, where this is so, the only satisfactory method of watering is to immerse the whole in water, with the result that slowly but surely the cone of earth becomes washed away and the plant, with many roots exposed, stands right out of the soil. Where, too,

likely to result. Choose, as far as possible, the "half way house," *i.e.*, the places between the ventilators, so that, while air may be circulating freely, it does not blow right upon them—a fatal matter for those of thinner composition, such as the pinnules of a young Maidenhair.

Choice should be made of suitable varieties, not only for baskets, but for the size of the house in which they are to be grown. The following are ideal for a small or medium-sized house. *Polypodium appendiculatum*, is a variety perfectly distinct from all others, with gracefully pendulous fronds, 15ins. in length. This is one of the most brilliant of all Ferns, for the leaves are green, with the mid-rib and veins of a deep crimson. To bring out the full quality of their brilliant colour the plants must be grown in a good light and a temperature of about 55°. *Asplenium flabellifolium* is at home in the temperature of the ordinary greenhouse and makes a most decorative plant, composed of pretty slender growing fronds, which are evergreen. These fronds are brown stemmed and very curious looking, while a bud is formed at the end of each that, immediately it comes into contact with soil, throws out roots and begins an independent existence of its own. A good specimen is necessary before you can judge the quality of the plant, for a small specimen is apt to look weedy. *Asplenium*

Sandersoni is another very fine small basket plant that does well in the greenhouse, making slender fronds, 6ins. to 9ins. in length, of thin, papery texture.

Among Maidenheads, *Adiantum caudatum* is quite distinct and makes fronds 1ft. to 1½ft. long that, where they come into contact with the soil, will root and form plantlets at the extremity. The pinnæ are produced upon either side of the mid-rib and it is most curious that, while they are fully developed upon one side, they are scarcely at all on the reverse. Both stems and leaves are thickly covered with light brown hairs. A variety of *A. caudatum*—*Edgeworthii* is very similar to this, but distinguishable by the fact that the fronds are quite devoid of hair.

A. lunulatum dolabriforme is a very handsome variety for the warm house and preferable to *lunulatum* in that it is evergreen. The fronds spring from a tufted crown on thin wiry stems that droop gracefully over, to a length of 6ins. to 1ft. These fronds are pinnate and proliferous at the end, so that plants may be seen carrying three generations at one time. Take special care with this that it never becomes dry or you will certainly lose it. *Blechnum glandulosum* requires the warmth of a house heated to 55° or 60° and consists of a creeping rhizome which bears beautiful spear-shaped fronds 1ft. to 1½ft. long, forming a very attractive specimen. *Davallias* provide a host of basket varieties, among those best suited to the small house being *D. dissecta*. This bears charming rusty brown rhizomes and a great abundance of finely cut fronds about 1ft. in length and triangular in form.

Among the unique Gold and Silver Ferns that display their charm to the fullest extent under basket culture, *Gymnogramme calomelanos argyrophylla* is perhaps the best of all. The fronds of this are 1½ft. long, the closely set leaflets being thickly covered upon both the under and upper surfaces with silvery white farina. Grown in baskets, both of these surfaces are exposed to view and the effect is both remarkable and really beautiful. Great care must, of course, be taken that this is not watered overhead or accidentally sprayed with the syringe or the splendid appearance will quickly be ruined, though, at the same time, the roots must have an abundant supply of moisture.

Turning from small baskets to larger ones and larger houses, where great size and length of frond is an advantage, one of the grandest features that are imaginable is supplied by *Polypodium subauriculatum*, a giant with fronds 8ft. to 10ft. in length. This demands the temperature of a warm house and bears rhizomes clothed with brown scales. In young plants the leaflets are slightly toothed, with older ones set widely apart. The plant does not like to be too heavily shaded and appreciates some chopped sphagnum moss in the compost.

Large plants of the wonderful *Nephrolepis*, in many varieties, form superb baskets in the warm house and, with their light green colour and almost endless fine division, always afford a picture of fascinating beauty. *N. acuta*, with its leathery pale green fronds, 2ft. to 4ft. in length, is very handsome and deserves special mention, while *N. davallioides furcans*, with its 3ft. to 4ft. long fronds springing from a cluster of crowns, should not be overlooked. Both of these appreciate a compost of coarsely broken peat, with some chopped sphagnum and silver sand. *Asplenium caudatum* needs a warm house and makes fronds 1½ft. to 2ft. in length, borne on firm stalks that are densely clothed with brown scales. The pinnæ are upon either side of the mid-rib and deeply toothed on the margin, while upon the underside of the margin are patches of red brown spores. H. W. C.-W.

CORRESPONDENCE

ROSE SPECIES.

I NOTICE that "Hortulanus," in a note on single Roses, expresses some surprise "that no one in this country seems to have conceived the idea of making a large and representative collection of Roses, single and double, in private gardens." I think I may fairly claim to have done something to remove this reproach. For some years past I have been collecting Rose species and I have in my garden to-day not less than 160 species or sub-species, and very interesting at all times of the year they are. I found that I had seven species which were not in the Kew collection. These I sent to Kew, the Curator on his side giving me a goodly number of species not previously in my collection. It is indeed strange that so few people seem to know of or to care for these Roses. It is a pity that there is no book suitable for the amateur on their culture, for Miss Wilmott's *magnum opus* on Rose species is far beyond the modest purse of most amateurs. Another difficulty in the way of making an adequate collection is the large amount of space required. Many of these Roses grow into very large bushes and it is not wise to use the knife on them too vigorously. But to grow them is an intense delight and they are beautiful even in winter, for the hips, which vary much in colour and form, make the garden quite gay even in December. The foliage of many of the species is very beautiful and a large number of them come into flower at least a fortnight before the procession of Teas and Hybrid Perpetuals. It is a bit of a business to collect these Roses. As you remark, Mr. T. Smith has a goodly number and some of the French rose growers can supply others. It is very easy to grow these Roses from seed, if one can get it. I find, e.g., that *Rosa Moyesii* and *Rosa hispida*, two of the most beautiful, grow very readily from seed. If such experience as I have had can be used to help any one desirous to form a collection of Rose species, I shall be very glad to give any information in my power to anyone who cares to write to me. I have, at any rate, learned a good deal from my own mistakes and have gained at least sufficient wisdom to realise how little I know when contrasted with what there is to know on this subject.—(REV.) R. W. CAREW HUNT, *Albury Rectory, Wheatley, Oxon.*

THE MADROÑA.

THE Madroña of the Pacific Coast of North America, *Arbutus Menziesii*, is a handsome species and one that might be planted more widely, since it will do in any locality where the common

Strawberry Tree (*A. Unedo*) survives. In its native country *A. Menziesii* will attain the stature of a tall tree, but here it is more often seen some 20 ft. to 30 ft. high. In general appearance it resembles *A. Unedo*, but the foliage is paler, fresher green and the leaves are larger and more rounded at the tips. At this season the Madroña is perhaps more beautiful than at any other, for it sheds its bark

THE MADROÑA, *ARBUTUS MENZIESII*.

in autumn as cleanly as a snake slips out of its skin, leaving the stem and boughs a warm terracotta or foxy red, and perfectly smooth, so that the contrast between this and the bright, glossy foliage is very delightful. The fruit is considerably smaller than that of *A. Unedo*, but is borne in much larger, grape-like clusters. Whether it produces this fruit as freely as does the Strawberry Tree I cannot say from actual experience, but it doubtless does so in favoured districts. Quite apart from this, however, the Madroña is a tree well worth the attention of all who can afford it a reasonably mild climate. It does well at Kew.—N. WILES.

THE TWELVE BEST SHRUBS.

THE results of the extensive and highly interesting correspondence on the above subject may, I think, be summed up both negatively and positively. In the first place, it has failed to tell us which are "the twelve best shrubs" or even to provide data for any judge or set of judges to settle that question. I have heard it asserted that there is no best flower, best book, best song

or best sermon, that every good thing has some special merit of its own. Be that as it may, it is impossible to say which are the best twelve shrubs, if only on account of differences of latitude and longitude—especially the latter—soil and situation, not to mention the truth of the Latin tag, *de gustibus non est disputandum*. What this correspondence has done, however, is to furnish readers of THE GARDEN with a list of several dozens of shrubs of very high merit from which it should be comparatively easy for anyone to choose a dozen which will prove to be really excellent for his or her particular circumstances. By the way, so far as my memory serves me, no list has included *Garrya elliptica* or *Skimmia japonica*, both beautiful in early spring in quite different ways.—CALEDONIA.

WITHOUT any qualifications regarding soils or hardiness, my choice of the best twelve shrubs for the average garden is as follows:—*Berberis stenophylla*, *Buddleia variabilis* *magnifica*, *Ceanothus Gloire de Versailles*, *Diervilla Abel Carrière*, *Forsythia spectabilis*, *Philadelphus Virginal*, *Ribes sanguineum* King Edward, *Spiræa arguta*, *Sophora viciifolia*, *Tamarix pentandra*, *Viburnum Tinus*, *Viburnum tomentosum* *plicatum*. A next best dozen would be of almost equal value, in fact, individual shrubs could no doubt be picked out which would be preferable to some of the best dozen for certain gardens. *Cistus cypricus*, *Escallonia langleyensis*, *Fothergilla major*, *Hamamelis mollis*, *Hypericum patulum* Henryi, *Kerria japonica* fl. pl., *Magnolia stellata*, *Olearia Haastii*, *Osmanthus Delavayi*, *Prunus triloba* fl. pl., *Rhododendron racemosum* and *Veronica Traversii*. A criticism of this list would be that half of the dozen are white, but as the flowering season extends from March to August it is not a defect in the garden.—A. O.

THE LOQUAT.

IN your issue of September 2 you refer to the Loquat (*Photinia japonica*) as follows: "They are usually considered more suitable for culinary purposes than for dessert." The Loquat is quite common here; in fact, I have one in my own garden, but I have never heard of it as a culinary fruit. It is principally esteemed because it comes in so early.—H. A. MARRISER, *Auckland, New Zealand.*

["For culinary purposes" might have been better expressed as "for jelly."—ED.]

GRAFTING CLEMATISES.

I NOTICE in your issue of November 11 an article by E. Markham on "Own Root Clematises at Gravetye." I should have expected to see such an article over the initials "W. R.," as it speaks of considerable pains having been taken there "over a period of many years," whereas I understand Mr. Markham has only been employed there the last few years. He also mentions the "Nippon Clematis," the name given by Mr. Robinson several years ago to C. Jackmanni. I have already explained in the press that these two Clematises are not synonymous. No unbiased person now thinks that they are.

In this article, as also in an article Mr. Markham wrote last May, he advocates layering instead of grafting, and stated in the latter, "if this method of increasing these beautiful climbers were adopted instead of the persistent practice of grafting upon the poisonous stocks of the Wild Traveller's Joy (*C. Vitalba*) and others, I am convinced that we should hear less frequently of the sudden collapse of these choice plants."

I am led to ask Mr. Markham if he has ever grafted any Clematises on this stock, because it he has done so, and has taken the trouble to watch

their development, he would not use such a ridiculous expression as "poisonous stocks." He would also know that instead of the stock killing the scion, the plant commences to grow as soon as the union of the scion with the stock takes place, and continues to gain vigour, and within a few weeks of being repotted, it forms new roots round the scion, which further assists in the growth of the plant.

Layering is one of the natural methods of propagation, and is well suited where a limited quantity of a particular plant is required, but I should like to know how Mr. Markham would raise 30,000 plants annually on an economical commercial basis by this process?

Mr. Markham also states, "I have frequently noticed that where plants on their own roots have, from one cause or another, been damaged above the ground line during their early growth, fresh young wood quickly appears and fills the vacancy. There is thus ample proof here that the loss . . . is wholly due to the practice of grafting."

Allow me to tell Mr. Markham it is no proof whatever, because if grafted plants are properly planted with the scion below the surface of the ground, the plants will send up fresh young shoots in a like manner.

As evidence of the fallacy of Mr. Markham's imbibed Robinsonian theory, that grafted Clematises only are liable to "die back," it may interest your readers to know that, when on a recent tour in France, I visited some of the growers of Clematises in that country, very carefully inspected their stocks and saw numerous instances, not only of the established layered plants having "died back," but also the layered shoots on the stools, and the stools themselves which had succumbed. A gentleman who has purchased these layered plants for some years also volunteered the information that most of his plants died.

Such being the case, will Mr. Markham kindly explain why these plants have been affected, if grafting is the reason for the "dying back."

Mr. Markham concludes his article by stating that the use in France of *C. viticella*, a native of that country, as a stock, is equally as harmful as *C. vitalba*. I should like to know how *C. viticella* can possibly be harmful as a stock for grafting hybrids of that species.

My experience of grafted plants, especially during recent years, is that the percentage of those affected has been very markedly less. A customer only this autumn informed me that a Clematis my firm supplied him with in spring 1921, had grown very vigorously this season and had produced 300 blossoms, in spite of the "poisonous stock," and I know of numerous plants which have been established for several years.—A. G. JACKMAN.

SOWING FREESIA SEED.

I HAVE been asked to say a few words about sowing Freesia seed in the late autumn. There is no use crying for the moon, so if anyone has missed the best time for sowing, which I think is the August or September after the seed has been gathered, he must make the best of it and get the seed in as soon as possible. It will take considerably longer to germinate, and possibly some seeds may fail, but only very few. One thing, however, is essential, the sower must make sure he has the seed garnered in the last summer—not older seed. About two years ago some was sent me from New Zealand, but it came up very irregularly and took a long time about it. I cannot say how long seed will keep good, as now I have always plenty of my own, but no doubt there is a time after which it is very little use. Anyone who buys from the 1923 seed catalogues ought to order it at once and get it sown as soon as ever they can.—JOSEPH JACOB.

A HARDY SUCCULENT.

IT is now a good number of years since I first saw *Cotyledon Semenovii* in a border of hardy flowers in the garden of a friend who has a special liking for such plants. It had not found its way into many gardens in this country at that time and was quite a rare plant. It has been long enough in cultivation in these isles, however, to have proved its suitability for our gardens, and I may add that the original plant referred to above is still in the border in the same garden and has considerably increased in size in the years which elapsed since it was planted. *Cotyledon Semenovii* is, possibly, more likely to find favour in the rock garden than in the border, where its genius seems less in agreement with its neighbours, but it is about 18 ins. high, so this must be considered when planting. It has the advantage of flowering in autumn—no mean consideration in the rock garden, where flowers are frequently less plentiful at that season. In general terms it may be described as a sedum-like, erect-growing plant with fleshy leaves and crimson flowers. Not all of the *Cotyledons* are true hardy perennial plants, many being only biennial, but *C. Semenovii* is a true perennial. It can do with a good rich soil, but it may also be grown in a poor, dry one, its succulent habit rendering it capable of standing a considerable amount of drought. It is increased by division, cuttings or seeds.—S. ARNOTT.

CERATOSTIGMA PLUMBAGINOIDES.

"*Ceratostigma plumbaginoides*."

Hark to the sesquipedalian roll!

Imagine the pride of the Greek-seeking gardener
When with *ore rotundo* he gets it out whole.

A plague on the fool who, immersed in his study,
Set a trap for the tongues of the folk as can't tell;
Why change the hard *Kappa* of Keras to Ceras?
There's a stigma attaching to his name as well.

"A Horn's prick which looks all the world like a
Fleawort"

(For *Plumbago* is *Leadwort* or *Fleawort* or both),
So there's the plain English of that high-falutin'
Which to most minds suggests a cutaneous growth.

You dear little Flower! Does it really describe you?
With your petals so blue, and your leaves all so red?
I believe that our fatuous botanist named you
As he lurched, none too steadily, up to his bed.

If I had my way we should spell that "Oh! Ideas!"
(For the printer *won't* see the two dots on the "i";
And from peers to princesses they all call it *oides*,
And they will call it *oides*, until they all die.

REGINALD RANKIN

SOIL STERILISATION. AN OBJECT LESSON.

THE question of sterilisation of soils is becoming pressing here on the Riviera. The Carnation in particular is so sensitive to a soil charged, as it were, with its own excreta, that it was thought impossible to grow this plant in the same place year after year. I do not say that very scientific methods are employed always, but at least it is universally understood that burning the old plants and baking as much of the soil as possible is absolutely necessary to success and much of the manure that was used has been found to be the very means of propagating fungoid disease. Above all, the stock itself must be free from this pest, and the seed is sterilised before sowing. The common white Madonna Lily is another plant found peculiarly liable to fungoid disease, which fully accounts for its failure in so many English gardens. The other day I was shown two pots of *Lilium*

candidum grown for early forcing, and those who have had to cultivate them in pots will, I feel sure, corroborate me when I say it has been a very uncertain plant to cultivate for forcing purposes. There were half a dozen pots at the end of the long row that looked unhealthy, so I enquired the cause. "Those are the few bulbs that were not planted in sterilised soil." The superb health of those in the sterilised soil was quite a surprise. The radical autumn leaves were so fine that the bulbs might have been grown for their foliage only, and the great fat central bud of the spiny flowering stems was clearly visible in mid-November. The lesson was to me very striking. The same soil—but not sterilised—spelt disappointment and defeat, the carefully treated soil spelt success. No fresh manure of any sort must, of course, ever be used to this Lily.—E. H. WOODALL.

THE HALSHAMBERRY.

TODAY (November 24) we made our last gathering of this most useful berry, sufficient good fruits to make a good-sized tart. I hope your readers will note the above date. We cut the plants hard down to the ground in February; they made extraordinarily prolific growth and have fruited from early in September right up to now. Plants of this *Rubus* were first sent me as a present by my friend Mr. King-Sampson of the Beacon Hotel, Crowborough. He grows a large breadth of it for use in the hotel, and told me of its abundant bearing and sterling useful qualities. I would not be without it now on any account.—F. HERBERT CHAPMAN, Rye.

"BEAUTIFUL FLOWERS AND HOW TO GROW THEM."

IN your issue of November 11 I notice with astonishment a critical review of a book by Messrs. H. J. and W. P. Wright. I do not know in what manner this is now being issued, but as it was published in 1909, there is every reason that it should appear "antiquated" to one who had not seen it before. It seems to me that the letterpress was chiefly meant for a setting to the illustrations, which you rightly label as "really beautiful." They are excellent reproductions from some of the first flower painters of that time, and alone make the possession of the book a delight. I confess I have never studied the letterpress, and, possibly, had your critic known its date he would have dealt more mercifully with it.—HUGGIRLEY.

[The book was sent for review without comment. It bears 1922 on the title page and there is nothing to suggest that it is only a reprint.—ED.]

WINTER GREENS BETWEEN OTHER CROPS.

THE practice, which so long held sway, of planting Winter Greens alternately between other crops—Potatoes mostly—for economy's sake finds few adherents to-day, as it has been proved conclusively time and again that there is no advantage whatever to be derived in so doing. The best winter greens are produced on ground (prepared for by deep digging and manuring) set aside exclusively for them, and it is when an attempt is made to wrest from the soil two strong-growing vegetables, often planted in close proximity to each other, that the folly is seen in poor crops from both. In no season are the baneful effects of close-cropping so clearly demonstrated as in a time of drought, as then both suffer. Winter greens, whether they be represented by Savoys, Brussels Sprouts or Kale, take so much from the soil as to need rich feeding and a reasonable amount of room, and it is the loss of this that brings about vegetables of

indifferent quality. There is no economy whatever in curtailing the root room of winter greens, which, after all, are an important item of food. Is it to be wondered at that the dreaded club-root now finds congenial conditions in which to spread quickly on overcrowded and ill-nourished ground?—W. L. L.

WINTER-FLOWERING BEGONIAS.

IT is rather surprising that these beautiful plants are not more widely grown for the embellishment of the conservatory during the dull winter months. Apart from the Gloire de Lorraine section their culture is unfortunately somewhat difficult. However, if care and a little forethought be exercised, a reasonable amount of success may be expected. Their usefulness as plants for the conservatory is emphasised by the large collection now on view in the conservatory (House No. 4) at Kew. An explanatory note accompanying this collection states: "Begonia socotrana was introduced from the Island of Socotra in 1880 by Professor Bayley Balfour of Edinburgh Botanic Gardens. This, in itself a beautiful winter-flowering species, proved of immense importance as the progenitor of our present day race of winter-flowering Begonias. From 1883 Messrs. J. Veitch and Sons produced

many fine winter-flowering varieties by inter-crossing *B. socotrana* with various tuberous-rooted varieties; some of their latest hybrids being Exquisite, Fascination and Optima, as shewn in this group. Note how their leaves resemble the offspring of the Audrean species. They have never been commonly cultivated, this owing to certain cultural difficulties. Mons. Lemoine of Nancy, in 1892, crossed *B. socotrana* with the S. African *B. Dregei*; the following year, 1893, they sent out the resulting hybrid, *B. Gloire de Lorraine*, of which there are now several varieties, including several of American origin, such as Glory of Cincinnati and Mrs. Petersen." Perhaps one of the most successful amateur growers of these Begonias is Sir C. Nall-Cain of Welwyn, as those who have seen his wonderful exhibits at the Royal Horticultural Society's Hall will testify. Apart from their value as pot plants, *B. Gloire de Lorraine* and its varieties are among the most useful of plants for basket work. Among the sorts to be seen at Kew are the well known and beautiful Optima, Exquisite; BB. Mrs. Heal, Scottiana, Bavaria, Ingrams, Gloire de Lorraine Mrs. Rothschild, G. de Lorraine Turnford Hall, polyantha (from Mexico), Miss E. Chibran, Sunrise, Fascination, Dregei, socotrana, Glory of Cincinnati, Sandera and Mrs. Petersen. An admirably grown and comprehensive collection!—G. H.

SEWAGE MANURE

ITS USE AND VALUE

IT is interesting to note that sewage manure (as such) is now being advertised in the gardening Press as a commercial proposition, but there will doubtless be a great many gardeners who read such advertisements, but who hesitate to purchase sewage manure from those who offer it, despite the acute shortage of dung in many districts, thinking that it will not give satisfactory results and thus serve no useful purpose, but be money wasted if it is used. Such fears are groundless and therefore the fullest use should be made of the material as a substitute for dung, since it is, with certain striking exceptions, quite a good one.

I have no wish to draw attention to my own work on sewage manure in connexion with manuring of gardens and allotments, as most readers have probably read the results of my experiments elsewhere, but I may say for the benefit of those who have not, that I went into the matter pretty fully quite recently and found that many of the objections to using sewage manure were hollow ones, and that it generally gave quite satisfactory results considering its somewhat variable composition.

If full use is to be made of sewage manure this winter and next year, what are some of the most important points in connexion with it? it may be asked. First of all I place the matter of price, and bearing in mind that samples are rarely as rich in fertilising material as an equal weight (not bulk) of dung, a low price should consequently be paid for what may justly be termed an inferior manure. I see it advertised at half a guinea per ton, carriage forward from London, in four ton truck loads, and this is the maximum price which should be paid. It will probably be found possible if the matter is taken up by the gardening public, to put it on rail later at 8s. 6d. per ton—one hopes so—as this would be a price that no one need hesitate to pay with the assurance that it would be money well expended.

I have not so far examined or tested samples of the sewage manure being offered as a commercial

article, so cannot speak definitely as to its composition. The samples used for my experiments were samples of the pressed sludge cake and other materials from actual sewage works and these were found on analysis to be very low in potash content. Therefore it was necessary to bring this up by adding potash in some form or other, the most economical material being shown to be ordinary factory flue dust. The actual amount to add varies obviously with the analysis of the sample of flue dust to be used, but my aim was to get about 4lbs. of potash into each ton of the sewage material. Considerably more could be used with advantage in the case of root crops and Potatoes, which are very partial to potash, but a 4lb.-per-ton-standard was shewn to be quite sufficient for ordinary work.

Now as regard the special soils most benefited by the use of sewage manure, the opposite takes place to what one would expect. Many casual observers of sewage manure either in its dried or undried condition would regard it as a good binding agent for light and chalky soils, but on the contrary it is an opening material much more suitable for heavy clay land than for light sandy soil and almost equally useful on strong marly ground. If an average sample be taken and rubbed in the palm of the hand it will prove to be far less sticky and greasy than one would expect, and in many cases abundance of sand can be noticed in it. This is exceedingly useful as an opening agent on strong soils, and advantage should be taken of the fact. Where, however, mechanical analysis (which can easily be carried out by any gardener who does not mind going to a bit of trouble), shews that there is more sand in it than 15 per cent., or at the very most 20 per cent., a considerably lower price should be paid for it, as one is paying for sand in such cases and not for manure.

The amount of actual humus in sewage manure varies between wide limits. I have had samples which, on being put through the process of mechanical analysis shewed that they contained as

much as 50 per cent. of organic matter. Average samples are generally much nearer 20 per cent., and on strong soils this is quite sufficient. I might mention that the samples richest in humus can be used with fair advantage on light soils, but that the humus appears to be very easily washed out of such soils, far more quickly than, say, the humus produced from decomposing vegetable manure.

Sewage manure often contains a large quantity of chalk, but this should never exceed 45 per cent. at the very most, since one does not want to pay for chalk at the manure rate. About 35 per cent. is a fair average, and a pretty good idea of the amount present can, of course, be obtained readily by testing the material in the well known way with hydrochloric acid. It is not necessary to give details of the method here. Dried sludge or dried sewage manure as it is more politely called, should not contain more than 5 per cent. of water, the wet material, of course, containing a variable and comparatively large amount of water (which by the way makes the carriage mount up).

I have used sewage manure so far to a limited extent only in the case of flowers, but with very good results in each case, it being proved quite suitable for the manuring of borders intended for and afterwards sown or planted with hardy annuals and hardy herbaceous perennials. Whether it will last as long as dung in the case of borders of the latter, which are left down for a number of years is, of course, impossible to say at present, but one hopes for the best. In the case of vegetables, with a few striking exceptions such as the more salading kind of vegetable, which roots in the surface soil and requires a very rich medium to give its highest return, sewage manure was shown to be of equal, if not greater value than dung, provided, of course, that it was not used too fresh, for it is then full of germinating weed seeds which give a good deal of trouble. Potatoes gave a heavy crop with it, and root crops generally, if supplemented with potash, could be grown with it of very high quality indeed. A poor soil could, it was shown, be brought up into a high state of fertility by its general use with very little danger of fanging the roots, whereas dung would fang them directly. Peas and Beans can be grown in trenches manured with sewage manure in just the same way as one would manure with dung, using slightly less of the material and not more, as some might expect. Cabbage crops were shown to do very well with it, but its use does not, unfortunately, cure clubroot disease, as some writers claim. On acid soils it appears to aggravate this disease, unless it contains a high percentage of lime, and it will probably also aggravate wart disease in Potatoes on land affected by that serious malady, as the two diseases are related. Land on which my experiments were carried out was free from wart, and I was unable to use it on any infected area to note its effects.

About how much should one use? That is a question which must, of course, depend very largely on the poorness or richness of the soil on which one is working. A good average dressing appears to be 2½ tons to 3 tons per 1,000 sq. yds., or under 14 tons per acre. This, compared with the weight of dung usually applied is economical both in quantity and price. Poor soils must obviously have more, and on very poor land (or one might say the poorest land of all), the amount could be increased by as much as 50 per cent., while on rich land it could be decreased in nearly the same proportion.

I hope this little sketch of the use, etc., of sewage manure will induce many other gardeners to take it up. I was very far from being disappointed with the results I obtained from its use, and have no hesitation in saying that other gardeners will be equally pleased if they will give it a fair trial.

E. T. ELLIS.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Roots in Store. particularly Onions, should be looked over when the weather is unsuitable for outside work and those found in an unsatisfactory state placed ready for immediate use. The bulbs did not ripen too well in this neighbourhood this season, and unless storage quarters are very good it will be impossible to keep them very late in the spring. Potatoes, too, need attention and tubers required for seed should be laid out thinly in shallow trays or spread out on a cool store stage, where it is convenient to look over them occasionally for disease, etc.

Uncropped Land.—Make the best use of dry days to get carting or wheeling of necessary manure on these plots done, so that, as opportunity offers, the work of digging or trenching will not be held up. It should be arranged so that the heaviest land receives such a dressing as decayed leaves, straw manure and decaying greenstuff, and the lighter soil such as cow and pig manure, etc. Throw the ground up roughly so that the weather may have full play upon it.

Autumn Sown Cauliflowers which were pricked out in frames must receive plenty of air whenever the weather is at all open, as any coddling of the plants will only spoil them, particularly so when such treatment encourages a close damp atmosphere. Stir the soil a little occasionally and guard against slugs. If no plants were potted up and it is desired to bring a few along more quickly, lift the more forward of them now and pot fairly firmly into 4in. pots.

The Flower Garden.

Protecting Plants.—It will be advisable to make the necessary arrangements for the protection of the various shrubs, etc., which will shortly need it, should a cold spell be experienced. A suitable protection may be afforded with matting material or with evergreen boughs. To fix whichever is chosen in position for single plants, or small groups, some stout stakes driven into the ground and fastened securely at the top will offer a ready means of attaching the covering. It may only be necessary in some cases to check the north and east winds having full play, and this may be dealt with by interlacing plenty of evergreen boughs in among some wattle hurdles made sufficiently high to suit the purpose. It should never be forgotten that to afford plenty of protection to the roots and base of the plants is of even greater importance than giving top covering in many cases, so, when dealing with any plants of doubtful or unknown hardihood, put a good covering of ashes round the plants and use some dry bracken fern in among the lower branches and around the stems. Shrubs on walls or against buildings are easily protected either with mats or boughs, taking care they are made quite secure against strong wind. Bush Roses needing protection may have some dry soil moulded cone-fashion round the stems, interlacing at the same time, if necessary, a little bracken among the shoots. Standards may have some of this material worked among the growths.

The Hardy Fruit Garden.

General Work.—If planting or root pruning has been held up, lose no time if the soil is workable in getting this finished. Place a good mulching of leaves and straw manure round newly planted Apples, Pears, etc., to keep them warm at the root. Should woolly aphid be attacking any of the trees, the present time is a suitable one for dealing with it, either with a strong spray or, better still, if time can be found, go over the affected branches separately with a good stout paint brush, taking care that none of the pests is overlooked. A paraffin emulsion preparation is as good as anything for this pest.

Fruits Under Glass.

Strawberries.—Plenty of time should always be allowed for bringing along the early batches of pot Strawberries, as hard forcing may easily mean the loss of the crop. There are several suitable places for giving the plants a gentle start, such as on shelves near the glass in a slightly heated fruit house, or in a moderately warm plant house in similar position, or again in a lean-to pit facing south. For choice the last named is the best, especially when it can be arranged for a bed of leaves to be placed in it. This bed of leaves, when made thoroughly firm, will give a gentle, regular heat, which is very helpful in encouraging the plants into a healthy, active state at the roots. The plants, having been cleared of decayed leaves, etc., and

had their pots cleansed and the drainage examined, should be stood on the leaves for about a fortnight when they may be plunged into them. Avoid excessive moisture for some weeks.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

General Work.—Remove all decaying leaves from among the Brussels Sprouts and Green Kale, so that more air may circulate about the plants. This assists in firming the stems and imparts a much tidier appearance to the garden. Swedes may be cleared from the ground and stored in suitable quarters for winter use. A quantity of Horseradish may also be lifted now and stored for convenience during wintry weather.

Mushrooms.—Beds spawned six or seven weeks ago will now be shewing freely so should have the straw covering removed. Successional beds should now be spawned and soiled down, keeping up an even temperature of from 60° to 65°. Excessive heat should be guarded against, it being wise to err on the low side rather than have the temperature too high. Spray the paths and walls close to the hot-water pipes morning and afternoon.

Parsley.—Where provision has been made for winter supplies by planting in frames, close attention should be given the plants in the way of free ventilation so that damping off of the leaves may be kept in check. Pick off all decayed growths and afford suitable protection during severe frost.

Perpetual Spinach proves a welcome addition to the winter supplies, being hardy and of free growth. Run the hoe between the rows at frequent intervals so that the surface soil may be kept stirred and thus encourage further growth while the weather is open.

Cauliflowers.—Young plants growing in frames for early planting require abundance of ventilation so that they may be kept from making too much soft growth as well as to prevent the leaves from becoming mildewed. Stir the soil between the plants with a pointed stick and keep the soil on the dry side during the dull winter months.

The Hardy Fruit Garden.

Red and White Currants.—When pruning Red and White Currants the side growths should be well cut back to two or three buds, leaving about 6ins. of extension wood where necessary. The cordon method of training these Currants is to be commended, as the fruit grown on cordon trees is generally of excellent quality and large size. A quantity trained on a north wall ensures late supplies, while the fruit can be more readily protected from birds and is easily gathered.

Black Currants should not be subjected to spur pruning as the finest fruit is produced on the previous year's growths. Retain a few of the best placed basal growths to take the place of old or exhausted branches which should be removed. Any young shoots of undue length should also be cut back, while bushes carrying dense growth should receive a judicious thinning, keeping the centre of the bushes open. In gardens where caterpillars have been troublesome during the past season the soil should be removed from beneath the bushes to a depth of 3ins. or 4ins., replacing it with fresh compost. A light dressing of newly slaked lime will prove beneficial to the roots and act as a deterrent to the many insect pests which attack fruit trees. A dusting of soot and lime should also be given the bushes as it renders the bark clean and bright.

Planting should be pushed forward whenever the state of the soil and weather conditions will allow. After planting apply a mulch of short litter or old hot-bed manure, as this assists in protecting the roots from severe frost.

The Flower Garden.

Early-flowering Gladioli always find favour where cut flowers are in demand, especially The Bride and Blushing Bride, two excellent and easily grown sorts. This section of the Gladiolus family rather favours a light soil, but on heavy land will do quite well if the bulbs are surrounded by a mixture of leaf-mould and sand more quickly to encourage root action. Plant the bulbs fairly closely and not too deeply. Choose a sunny position for the bed. JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Oranges are what the gardener usually describes as "dirty plants," and not without good reason, for they are very subject to attacks of scale and mealy bug; both of them troublesome pests, the former especially being difficult to keep in check. The best preventive I know of is a paraffin and soft soap emulsion, with which they should be sprayed once a week. If the plants are in pots or tubs, they should be laid on their sides to prevent the liquid running into the pots; if the plants are planted out in beds or borders, it is wise to lay old sacking or some such material on the surface of the border. During wet days some of the outdoor staff should be put on to sponge the plants thoroughly. Oranges are not much in favour at the present day, yet their blossom and fruit always attract attention, and they are really among the best of evergreen shrubs for furnishing the conservatory as, beyond keeping clean, they require very little attention. They are excellent for growing in tubs, but are possibly at their best when planted out in beds or borders in a cool conservatory. Pruned and trained in much the same way as Peach trees they are excellent for covering walls. Oranges enjoy a rich medium loam, and when potting or top-dressing plants a 6in. potful of fine bone-meal should be added to every bushel of soil.

Paraffin and Soap Emulsion.—There is possibly no better or more effective insecticide in the garden than paraffin, when properly and intelligently used. On the other hand, this is one of the most dangerous insecticides when improperly emulsed. Even at the present day it is surprising how often when its use is advised one reads something like this: "Mix a wine-glassful of paraffin in a bucketful of soft soap and hot water, and when applying it have an assistant to keep it constantly agitated with a syringe." This is a more or less useless precaution, as the mixture is no sooner sprayed on the plants than the oil separates out again. It is unnecessary to run this risk of injury to plants, as it is quite easy to make a safe emulsion in either of the following ways: Take 1½lb. of soft soap and place in an old pot or bucket with half a pint of water. Place on the fire and when dissolved remove from the fire and add 1 gallon of paraffin, stirring until it thoroughly combines with the soft soap. This may be put away in tins or jars, and will keep for any length of time without the oil separating out. The other way is to mix them cold, working the soft soap and paraffin together until they combine. It is not so quick as the former method, but there is no doubt about their perfect combination, as this mixture will blend with cold water like milk and never shew a trace of oil. With the above emulsions 2ozs. to 1 gallon of water may be safely used for most plants, but of course the quantities must be varied for different classes of plants; the age of the foliage must also be taken into account. Whenever possible soft water should be used for mixing insecticides, and they are always more effective when applied warm. In fact, boiling water alone is an excellent insecticide, and it is surprising the number of plants that will stand spraying with "boiling" water. Of course it is not boiling by the time it reaches the plants through a fine spray.

Choisya ternata (Mexican Orange Blossom).—This shrub, although hardy in the open in many localities, is worth growing, especially in the colder parts of the country, for conservatory decoration. It flowers freely in small pots, and makes fine specimens when grown in large pots or tubs. It is easily rooted during the spring by means of short, half-ripened shoots, standing them in a close case in a cool house, or cuttings may be dibbled into a cold frame during the autumn. Such cuttings should make nice plants the following season.

Viburnum Tinus (Laurustinus).—This is also very useful for furnishing the cool conservatory, and along with the Choisya is excellent for unheated houses. This Viburnum is fairly hardy outdoors in the London neighbourhood, especially on light soils. It flowers more or less from September until March, according to the state of the weather. We, in the more favoured parts of the country, are, I am afraid, somewhat apt to forget our friends in less favoured parts. Hence plants that we have come to look upon as common outdoors may under less favourable conditions be well worth the shelter of a cold house. This is my reason for mentioning what to many may seem common plants. The newer Viburnums, Carlesii and odoratum, have so far proved hardy in the South, but here in the open the flowers of the former nearly always get more or less damaged

by spring frosts. It should thus be an ideal plant for an unheated house in the North.

Jasminum nudiflorum (Winter Jasmine).—Well grown specimens in pots of this common plant are very charming for a cool or unheated house.

J. COULTS.
Royal Botanic Gardens, Kew.

OBITUARY

HENRY JOHN ELWES.

THE death of H. J. Elwes, F.R.S., at his residence, Colesborne, at the age of seventy-six, severs another of the links which connect the Victorian giants in the world of horticulture and botany with the students and adventurers of this post-war age. A great traveller, Mr. Elwes was a horticultural authority of the first water. His monograph on the genus *Lilium*, published in 1880, is still a standard work. In collaboration with Professor Henry he produced "The Trees of Great Britain and Ireland," which was issued in seven volumes (1906-1913). This is a magnificent and monumental work and must have necessitated a vast deal of labour, but Mr. Elwes possessed application in marked degree, as well as the capacity for taking infinite pains to verify information. Upon the labour he devoted to the hybridisation and improvement of the Nerine there is no need to dwell. It is to some extent dealt with on another page. Mr. Elwes had a fine collection of Succulents at Colesborne and his collections of the smaller bulbous plants, such as Crocuses, Snowdrops, Fritillarias and Tulips, were well known and many of the species were collected and introduced by himself. Why particularise, however? He had a comprehensive knowledge of all branches of horticulture and was an admirable botanist.

He was a traveller in the best sense of the word. There was nothing of the Cook's tourist about Henry J. Elwes! From Asia Minor to far-off Japan and from India to Siberia, there were few extensive regions of Asia which he had not explored. North America, including Mexico, was also familiar ground to him. Nor did he neglect Europe to wander afield. Few living Englishmen know as much of the different European countries as did the man whose loss we lament. The plants he introduced would alone furnish a respectable catalogue!

A Fellow of the Royal Society since 1897 and a Victoria Medallist of Honour, he was largely instrumental in bringing about the resuscitation of that venerable and important publication the "Botanical Magazine." As gardeners we are apt to think of Mr. Elwes as a great collector, gardener and botanist, but, in truth, his interests were infinitely wider. He was, in 1921, elected President of the British Ornithological Union and contributed as long ago as 1873 an important paper "On the Geographical Distribution of Asiatic Birds." He was also a Past President of the Entomological Society, his interest centring principally on the lepidoptera.

His interests, when at home, were not entirely confined to his collections of trees and plants and his scientific pursuits, for he was fond of hunting, and in his younger days was an adept with the rifle. There are, indeed many quarters from which his massive frame and resonant voice will be sadly missed.

SIR ISAAC BAYLEY BALFOUR.

We hope in our next issue to publish an appreciation of Professor Sir Isaac Bayley Balfour, K.B.E., F.R.S., who for many years was Regius Keeper of the Edinburgh Botanic Gardens and Professor of Botany at Edinburgh University. His death at the age of sixty-nine occurred at Court Hill, Haslemere, on 30th ult.

The Blueberry.—For a moist but not heavy loam or peaty soil the Blueberry of America, *Vaccinium corymbosum*, is an admirable shrub, attaining a height of some 8ft. or more and spreading to fully that width. It is a deciduous species, and the fresh green leaves of spring are followed by clusters of pendent waxen bells in a clear pink. In the later summer the blue and luscious fruits ripen, and these are said to be as good to eat as they are to look upon. But *V. corymbosum* is, perhaps, most noteworthy as an autumn foliage shrub, the leaves assuming a vivid blood red before they fall.

The Sensitive Fern.—The North American species, *Onoclea sensibilis*, is a Fern which merits a wider popularity than it now enjoys, for there can be few plants more delightful for a cool, rather moist spot in partial shade. *O. sensibilis* is remarkable for the beautiful, soft emerald-green of its bluntly-lobed fronds, especially when these first appear in spring, while the warm, even shade of golden buff which they assume in autumn is hardly less attractive. This Fern is most suitably placed among the more lowly peat plants, or in a cool bed where it can be associated with such as hardy Orchises and Cyclamens, dwarf Anemones and any of the smaller spring-flowering bulbs that will do in such conditions. Spreading by means of underground rhizomes the Sensitive Fern will cover thinly a considerable space, but it is not generally a rapid or in any sense a rampant grower. The height of the fronds is about 1ft., but this varies considerably according to soil and moisture.

The Cockspur Thorn.—A tree somewhat little known yet of great decorative value is the Cockspur Thorn, *Crataegus Crus-galli*. Perhaps the most valuable characteristic of this tree is the remarkable beauty of its autumnal foliage. With the "fall of the year" the leafage assumes various and wonderful tints of fiery red, golden and sulphur yellow and intermediate shades of fawn, thus forming an effect both brilliant and artistically harmonious. It should not be supposed that this autumnal display of splendour terminates its season of beauty, for with the falling of the leaves the handsome bright red berries are revealed. These are considerably larger in size than the majority of Thorn berries and measure about half an inch in diameter. The berries continue to adorn the branches for the greater part of the winter. With the coming of spring the tree is again beautiful with fresh green leaves and white blossom. This *Crataegus* forms a tree of but moderate size, seldom exceeding some 20ft. in height. It can therefore be relied on not unduly to monopolise space even in quite small gardens, where it might very advantageously displace the unsuitable specimens of common Poplar, Lime, etc., too frequently met with. The Cockspur Thorn has been so named on account of the curious shape of the long thorns on the branches. *Crataegus Crus-galli* is a native of North America. It requires little or no attention in regard to pruning and is also easily catered for in respect to soil, for it will thrive on almost any ground of moderate fertility.

Rose Trials at Wisley. The Director of Wisley has the pleasure to say that the land set aside for the rose-trial ground in the Gardens of the Royal Horticultural Society is now ready for planting. He would be glad if those desiring to send Roses for trial this season would let him know as soon as possible, and will be pleased to send the necessary entry forms. All types of Roses will be included in the trials. All communications should be addressed to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey. (Goods: Horsley, L. and S.W.Ry.)

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

PLANTS FOR A MIXED BORDER (C. M. W.).—Our correspondent must not enrich the soil unduly if the plants are not to grow too high. The following, if planted in a soil of medium richness, will attain to the desired height. For the back of the border use *Eryngium alpinum*, *E. campestre*, *E. Bourgati*, *E. tripartitum*, *Aster amethystinus*, *Aconitum Fischeri*, *Echinops Ritro*, *Campanula E. Molyneux*, *C. Van Houttei*, *C. carpatia Riverslea*, *Centauria montana*, *Aquilegia hybrida Cœrulea* in variety, *Scabiosa caucasica*. For centre, the seven last named will be ideal. For the front, next to the Nepeta, use the following: *Gentiana Andrewsii*, *G. Crucjata*, *G. macrophylla*, *G. purpurea*, *G. scabra*, *Anemone apennina purpurea* and *Violas*. These are all blue. Lilac, violet or purple colours will be available in *Asters*, *Dolichiums*, *Iris*, *Fynthrum*, *Gentiana* and *Aubrietia*, sufficient to fill a very large border with a good range of the various shades required.

ROCK GARDEN.

PLANTS FOR A ROCKERY FACING NORTH-EAST SHADED BY TREES (R. C. C., Worcester-shire).—With such an aspect one could not expect to get a great display of colour, but many things will grow in such a situation. Among the dwarfier plants are *Anemone nemorosa*, *A. apennina*, *Omphalodes verna*, *Campanula Portenschlagiana*, *Corydalis bulbosa*, *C. nobilis*, *Centauria montana*, *Crucianella stylosa*, *Epimedium pinnatum*, *Eranthis hyemalis*, *Heuchera brizoides*, *Myosotis alpestris*, *Ophiopogon spicatum*, *Polygonatum multiflorum*, *Convallaria majalis* (Lily of the Valley), *Polygonum affine* (Brunonis), *Potentilla nepalensis*, *Primula rosea*, *P. japonica*, *P. Bulleyana*, *P. Jacquiniana*, *P. sikkimensis*, *Pulmonaria azurea*, *Sedum spurium* (purple and white vars.) and *Thalictrum aquilegifolium*. A reliable firm of nurserymen near who would supply the above is Messrs. Bowell and Skarrett, Cemetery Road, Cheltenham.

TREES AND SHRUBS.

PRUNING LAURELS (M. H., Grisy-Suisnes).—In the ordinary way an established Laurel bush or hedge is one of the easiest things to prune, as it produces young shoots so freely from the old stems when cut down in April or early May. A recently transplanted hedge is not so easy to deal with. We should, however, not hesitate to reduce the height now to 8ft. or 10ft., even lower than this if the stems at this height are not more than 2ins. to 3ins. through. It would serve no useful purpose to tie the branches together, but rather shorten them back to a reasonable length. As a drastic cutting is suggested now, there will not be a great deal of pruning to do in spring beyond shortening back all the thin straggling shoots. Where thin at the bottom cut down one or two of the thicker stems, if possible, to within about 2ft. of the ground. Tar over all cut surfaces. During dry weather now or later, especially if the ground is light, water the Laurels liberally until rooted well in the new positions.

MISCELLANEOUS.

YARROW IN LAWNS (P. L., Southminster).—Rake out the Yarrow and apply, in March, lib. of sulphate of ammonia to each square rod of lawn.

HOW TO TREAT POOR LAWNS (K. E. T.).—Evidently the soil of our correspondent's poor, weedy lawn is not of good quality and is possibly of a light nature. Such lawns require substantial top-dressings of rich material, and the present is a suitable time to apply them. Half a pound per square yard of the burnt rubbish will do good. Procure some well rotted manure, break it up very fine with a garden fork; to each bushel add two of rather retentive loam, also well broken up, and apply the mixture at the rate of one barrowload per square rod. From time to time brush the mixture to and fro; by next February it will have disappeared. At that time apply bone-meal at the rate of 3ozs. per square yard, and during next summer the lawn will look quite nice and fresh. First, however, uproot all coarse weeds. Do not use sand nor sulphate of ammonia.

SOWING SEEDS OF BULRUSHES (F. C., Alford).—The seeds ought to be quite ripe now; if not, the stems should remain in water till the heads break up easily. For sowing a place must be selected about water-level, but care must be taken that the water does not wash the seeds away after being sown. Sow the seeds at once in drills and slightly cover with soil, or the seeds may be pressed into the muddy soil with a flat board. The best and surest way to establish fresh groups of Bulrushes is to transplant them. If the level of the water can be lowered, then they may be got at more easily, but it is generally possible to get a few clumps at the water edge. The roots run rather deep, so care must be taken to get as much of them as possible. Another method is to take growing points with a few inches of the underground stems attached and plant them firmly in muddy soil. They must be kept very wet.

NAMES OF PLANTS.—H. P., Somerset.—1, *Carpinus caroliniana*; 2, *Nellia (Spiraea) opulifolia aurea*.

NAMES OF FRUIT.—A. K., Liphook.—1, Winter Quarrenden; 2, Foster's Seedling; 3, Blenheim Orange; 4, Tower of Glamis; 5, Royal Jubilee; 6, King of the Pippins.

THE ARRANGEMENT OF FLOWERING SHRUBS—II

(Continued from page 601.)

THE diagram at the top of page 628 shews how planting by families may be carried out. Flowering trees of some, such as many of the *Pyrus* family, for example, may be more conveniently grown in plantations if it is desired to grow a collection. For the garden of limited acreage, however, collections of trees are too bulky and the gardener, if collect he will, must be content with some of the shrub families. It is neither necessary nor desirable to change the character of the groupings quite suddenly. It would be unwise in the same bed, for example, suddenly to stop a collection of *Berberises* and *Thorns* and replace them with *Viburnums* and *Mock Oranges*. It is not wise, either, to have the opposite sides of a pathway entirely different in character. To do so gives an arbitrary unnatural effect.

It is not essential to arrange shrubs in the semi-wild manner indicated. Many of them may be grown successfully in open woodland, notably some of the *Rhododendron* species and other families on the borderline of hardiness. If existing woodland is not at disposal, a certain amount of shade and shelter should be provided as quickly as possible for the *Rhododendrons*. *Birches* and *Scots Pines* are suitable companions for them and afford the kind of shade they like, but the *Birches* are not specially quick growing and *Scots Pines* do best when planted small. For affording satisfactory shade quickly we are driven to *Willows* or *Poplars*, which both grow with exceeding rapidity. *Willows* do best when sets are planted rather than growing trees. More suitable permanent planting should be put in as well, however; the *Willows* and some, it not all,

of the *Poplars* may then be cut out when sufficient other shade is available.

To turn again to woodland planting, from the point of view of effect, one of the commonest mistakes is to plant too thickly. Thick planting of one particular species or variety to produce an immediate effect is, in the case of *Rhododendrons*, understandable and excusable, for they may be thinned before becoming overcrowded and will readily transplant to other quarters. The thick planting to which exception is taken is the overplanting of the whole area so that there is, at last, far more undergrowth than open woodland. From a collector's point of view and where space is limited this thick planting may be justified, but real woodland pictures are not possible under such conditions. The most satisfactory woodland gardens are oft-times those which contain least undergrowth. Even then it is not wise to confine such under-planting to shrubs. There is a host of herbaceous species which are wonderfully effective and which either do not restrict the view or confine it much less

than do evergreen shrubs such as the *Rhododendron*.

Flowering shrubs should never be planted in rows—either straight or curving—unless they are intended to form a hedge, in which case the fact that it is a hedge may be plainly indicated, or it may be made apparent on one side, the other side being disguised by an irregular massing of shrubs, including masses of the same variety, against it. In the more or less ordered planting suggested in our plan it is permissible to form clumps of a particular species or variety and leave it at that, but in the woodland a more natural arrangement should be sought, which means that the planting, even in the same group, will differ in thickness. Here it will be quite thick, yonder quite sparse, and on the margins little colonies of the same species may be found a short distance apart from the main grouping. Such planting is easy to describe but far from easy to arrange well. It can only be learned by a study of natural effects, and, even then, leaves a good deal of scope for imagination, since the effect when the plants have grown, will be entirely different from that which prevails when planting is first completed.

Reverting to the planting of the more ordered shrub garden, it is necessary to qualify to some extent the permissibility of planting single clumps of a species or variety. If for any reason one species stands out from the rest in the shrubbery to, as it were, form a *motif* in the arrangement, such planting will be far more effective if repeated at least once, though not on the same scale. In considering whether a species will stand out in this way it is necessary to bear in mind its flowering-time, since a kind which might be quite ordinary if it flowered,

A GROUPING OF AZALEAS.

say, in May, may be exceedingly prominent and noteworthy when it actually does flower a few weeks later. To take a concrete example, there are so many Mock Oranges that there is certainly no need thus to repeat any of the general run of species or varieties. *Philadelphus grandiflorus*, however, flowers when the other species are over,

and one might do worse than treat it as a unifying factor to be repeated in any border into which it is introduced

Berberis Darwinii and its hybrid, *B. stenophylla*, are outstanding shrubs, but there is no absolute necessity to repeat them, because there are several excellent forms of *stenophylla* which

are sufficiently like the typical plant to reproduce the effect.

In Fig. 2 is shown a planting scheme for a small garden. Trees and the larger shrubs are omitted from this scheme not only because of the space they take up but because it is impossible really to appreciate them unless one has space to stand far enough away to see them as a whole. In a limited space, too, they are likely to cast excessive shade. The only plant included which approaches tree stature is the slow growing *Eucryphia*. Even this might have a moderate growing *Cotoneaster*, such as *C. applanata*, substituted for it. The Broom family is a particularly valuable one for the small garden where the soil is suitable. The chief drawback to the race is that many of the most attractive forms are short-lived. This particularly applies to the forms and hybrids of the Common Broom, *Cytisus scoparius*. This shortness of life is often charged to grafting on a *Laburnum* stock, a practice which is certainly undesirable, but the truth is that the Common Broom on its own roots—from seed, for example—is anything but long-lived. It grows quickly and forms a rather open, irregular bush, the main stems become brittle and shew other symptoms of senescence, and if a snowfall does not wreck the bush, which it is likely to do, it ceases to make healthy growth and becomes dowdy and worn out. It is unwise, then, to make the clumps of these Brooms so large that their removal will make a very conspicuous gap or to place the forms of *C. scoparius* in juxtaposition. The White Broom, *Cytisus albus*, is, compared with the Common species, a long-lived plant. It usually produces a small forest of seedlings also, which grow happily enough in its shade, so that it is often possible to cut out an overgrown bush from a clump without in any way disfiguring the border, though for perhaps one season there may be a little shortage of flowers

Many of the shrubs suggested are too well known to need any reason stated for their inclusion. This will not be true, however, of *Ribes speciosum*, which, though long introduced, is not common in shrubberies. It is the most interesting member of a rather commonplace family. It does not make the splash of colour of the American Currant, *Ribes sanguineum*—few shrubs do—indeed, one would describe it rather as a Gooseberry than a Currant. The arching stems are heavily and picturesquely armoured, the foliage is neat and agreeable, and the long, tassel-like, bright crimson flowers very charming. The tassel-like effect is produced by the four red stamens which protrude the better part of an inch below the calyx. It has a reputation for being tender, but this hardly seems to be deserved, though it is true that it is long enough since we had a really hard winter.

Prunus triloba is best grown on a short leg. It is easy then to keep down the stock which, otherwise, is likely to smother the bush. The necessity for working it on an alien stock is the main objection to an otherwise admirable shrub. *Ceanothus Gloire de Versailles* is too well known to need praise. In cold localities it often fails unless given the shelter of a wall. *Gloire de Plautières* is hardier and should be given a trial in such case. It is not so fine in truss and, a shade deeper, scarcely so effective in colouring, but invaluable, nevertheless, where "Versailles" will not succeed. *Osmanthus Delavayi* is an admirable shrub for small gardens. Very neat and slow-growing, the tubular creamy white flowers are really beautiful, and though the shrub as a whole when in blossom could not be called showy, it is really effective. Quite young plants flower freely. It appears to be entirely hardy. The blossom is fragrant.

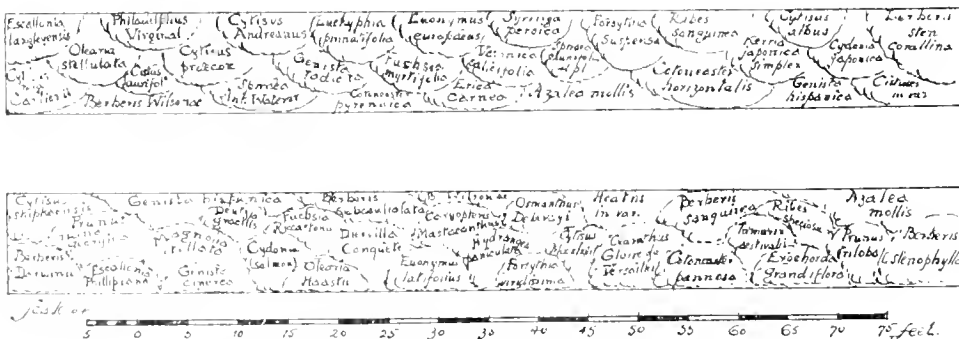

FIG. 2.—SHRUB ARRANGEMENT FOR A SMALL GARDEN.

THE CULTURE OF JAPANESE LILIES

AT this season of the year Japan-grown bulbs of the varieties of *Lilium auratum* and *L. speciosum* arrive. Dutch-grown bulbs have been on the market some time, but do not, size for size, give such good results as those from Japan. It is fairly easy to obtain good results with these Lilies for one year either outdoors or under glass. It is far more difficult permanently to establish them in the garden. Yet it is just this which most gardeners ardently desire to do. The novice is always proud of his spring display of bulbs, but to the seasoned gardener there is small joy in extracting from a bulb what another skilled grower has put into it!

Permanent success with these Japanese Lilies depends to very great extent, it must be admitted, upon climate. It is comparatively easy to persuade even *Lilium auratum* to flourish in South-Western Scotland. It is exceedingly difficult in the North Midlands and Eastern Counties, yet with skill and care it may be managed in most districts. The advice usually given is to plant the bulbs among Rhododendrons or other American plants. It is not possible to suggest a more likely situation, always provided that the Rhododendrons are in the half-shade which they love. It is quite possible to grow Rhododendrons successfully in full sunshine, if only the ground is well cultivated in the first instance and water is plentifully applied in times of drought. Cold water from the main or even ice-cold well water (so it be lime-free) will answer for the "Rhodos." Cold water, however, in hot weather is little better than sudden death to Lilies. Even sudden falls in the temperature, to which we are but too prone in this climate, are liable to prove disastrous. Their effects, however, may be largely overcome by screens of shrubs and trees. Fairly open woodland suits these Lilies well, but it must not be too dry nor yet in the least boggy. Wet land suits some Lilies admirably—the Panther Lily, *L. pardalinum*, to wit—but sharp drainage is essential for these Japanese kinds.

Of the several varieties of *Lilium auratum* some are more robust than others, and so more likely to establish themselves outdoors. Beginners with this flower should try first of all the typical form and the robust variety *platyphyllum*. Some find the latter easiest of all to manage, either outdoors or under glass. It is a handsome sort with fine foliage and large white flowers with a golden band down the centre of each petal. Of the *speciosum* (*lanicifolium*) varieties the easiest

is the form called *roseum*. *Melpomene* and *magnificum* seem to have less inherent vigour. *Speciosum album*, as generally sold, is a poor thing, but *album Kratzeri* is a fine and vigorous form and succeeds outdoors better than many of the highly coloured varieties. None of the *speciosums* has the abounding vigour of the beautiful yellow *Lilium Henryi*, which, except in colour, they so much resemble. It is, nevertheless, quite feasible to establish them outdoors even in the Midland Counties. Indeed, the writer has succeeded outdoors even with bulbs which had previously been forced!

A FINE SPIKE OF *LILIAM AURATUM*.

A moderately light but rich soil, well drained, in half-shade, preferably a westerly exposure with shelter from the east and north, will go far to ensure success. Bare ground is hateful to these stem-rooting Lilies. Some fairly light-growing annual or biennial plant should be encouraged to grow among them. The Pink Campions of our woodlands (*Lychnis diurna*) answer well, but there are many other things, including hardy Ferns, which are equally satisfactory; indeed, the Ferns are infinitely tidier and provide a better contrast when the Lilies come to flower, but they should not be planted in straight rows nor religiously spaced quincunx fashion. Let their arrangement correspond as nearly as possible with that in which Nature has a hand! The same advice will, needless to say, apply to the disposition of the Lilies themselves.

The *auratum* Lilies are more difficult to establish than the scarcely less magnificent *speciosum* forms,

but similar conditions are the best we can do for them. If there be boggy ground near and the air in summer is usually well charged with moisture, so much the better. Bitter winds are, perhaps, their worst enemy.

It is usual to "bed" the bulbs upon a layer of clean sharp silver sand and to scatter some around and over the bulb before replacing the mould. The idea is to keep at bay fungoid pests which might damage or destroy the dormant bulb. Once the bulb starts into growth the rapidly extending spike must take care of itself, but it is very soft at this time and easily damaged not only by disease but by animal agency. Experience shews that the sand *does* increase the chances of the bulb's success, but it must be quite clean and rather coarse to be beneficial. Some of the loamy materials which often masquerade as builders' sand could render no possible service and might easily do great harm.

The culture of Japanese Lilies in pots presents no real difficulty. The size of the pots used will depend very largely upon the diameter of the bulbs obtained. Five good-sized specimen bulbs may be grown in an 8½ in. Chrysanthemum pot and three large *auratum* bulbs may be accommodated in a roin. pot. Very often, however, it is necessary to use receptacles of handier size. A single bulb of *auratum* can be grown well in a 7 in. pot, and with very careful cultivation it is possible to get good results with one 6 in. in diameter. A 6 in. pot should easily bring one *Lilium speciosum* to perfection. Whatever sized pot is used, it is important to leave space for top-dressing as the stem-roots develop. If a very small pot is employed, it may be necessary to afford this extra space by adding a zinc collar to the pot-rim. The compost should consist of good sweet fibrous loam two parts, thoroughly decayed manure—spent hot-bed manure will do—one part and leaf-mould one part, with sufficient clean sharp sand to ensure porosity. A few lumps of charcoal are a useful addition. The drainage must, of course, be adequate. It is well worth while to sterilise the compost (by baking) before use. The opportunity which is afforded for treating composts against pests and diseases is the greatest advantage which the grower of hardy plants in pots has over his neighbour who trusts his stock to open border or rock garden. The pots should be given a good watering and be covered with leaves or other moisture-retaining material and placed in a frost-free pit or cold house until root action is well established. Once good growth below ground is under way, these Lilies will stand a fair amount of heat, but it must always be remembered that the greater the heat given the softer the growth becomes, and the more susceptible the plants get to chills from cold draughts or a fall of a few degrees in the temperature. Lilies, too, lose a great deal of character when forced and, unless for some special purpose, it is better to grow them on quietly but steadily in a cool greenhouse. They must not, in any event, be stood near hot-water pipes, as uneven heating and draughts of variable temperature are sure to occasion ill-health. A look-out must, of course, be kept for green fly, though these plants are no more subject to aphid attacks than the generality of greenhouse plants.

Top-dressing is important, and should have attention immediately the stem roots make their appearance. The compost used should be similar to that employed for potting, and should, when applied, be as nearly as possible the temperature of the house in which the plants are growing. After what has been written it is hardly necessary

to point out that the water given should be soft and rather higher than lower in temperature than the house. Water should be given sparingly until rooting is well established, though the soil must not entirely dry out as it might, with advantage, for Perpetual Carnations, for example. Afterwards, when in full growth, a great deal of water is required, but even then generous soakings "all round" are not desirable. The separate pots

should be watered "on their merits." Feeding may be practised—for plants in small pots it is essential—but it must be done with discretion. A light top-dressing of Clay's Fertiliser is often employed and answers well, or a very weak decoction of sheep-dung may be used. Weak soot-water is also beneficial. Always water with plain water immediately before giving the feed.

are ovate and as much as 5 ins. long. In pauperatus, the form illustrated, they are ½ in. or so long and narrow. There are several intermediate forms. The plants are uni-sexual, the flowers about ½ in. across, whitish in colour and very fragrant, the fruits reddish.

A FEW FLOWERING AND FRUITING BRAMBLES

THE most beautiful of flowering Brambles is, beyond doubt, *Rubus deliciosus*. This reaches a height of 6ft. or 8ft., sometimes more, and has arching canes which peel effectively and are quite thornless. The rather black-currant like leaves are downy beneath, and, when young, downy on the upper surface also. The flowers are a couple of inches across and pure white. This is an eminently desirable but still not common hardy shrub.

The Wineberry, *Rubus phoenicolasius*, is a well known and beautiful shrub, admirable in winter with its ruddy many-prickled arching canes, and also in late autumn when the red and yellow fruits on the complicated hairy calyces contrast with the still expanding flowers. The flowers themselves are white or pinkish, but small and rather inconspicuous, but the coloured calyces render even the unopened buds beautiful. The foliage is adequate and improved by the whitish colouring of the underside.

Of the many species the fruits of which are called Blackberries the most handsome (and, incidentally, probably the best for eating and cooking) is the Cut-leaved Blackberry, *R. laciniatus*. The flowers are white and the fruits, which are produced in handsome sprays, glossy black, large and ornamental, but the beauty of the plant largely resides in the large and elegantly cut foliage, which reminds one of the dissectum forms of *Acer palmatum*. This Bramble may be allowed to mound itself over a rough framework of timber or shrubs of small value, or it may be used effectively on a fair-sized pergola. It is unsuited for "close quarters," as the long canes are very formidably armed.

The Low Blackberry, *Rubus canadensis*, with practically thornless shoots, is handsome when in flower in early summer. The flowers, about an inch across, are white, but there is a form, or perhaps a hybrid, with pretty pink blossoms.

Rubus bambusarum is an evergreen climber which, when first introduced twenty years or so ago, made something of a sensation. It is

THE ALMOST LEAFLESS "WAIT-A-BIT" BRAMBLE, *RUBUS AUSTRALIS PAUPERATUS*.

interesting enough, and when trained up a pillar or tree trunk quite handsome, as the slender branches arch themselves very prettily. The flowers are insignificant. The beauty of the plant, such as it is, consists in the arching branches already referred to, the black fruits (edible) which are rather well displayed, and the whitish felting beneath the leaves which contrasts well with the deep green of the smooth upper sides. *R. Henryi* is in many respects very similar.

The Lawyer Vine, or Wait-a-bit of the Australian bush, *Rubus australis*, is a very variable species, the most remarkable form of which—var. *pauperatus* is, fortunately, the hardiest. Even this, however, is unsuitable for cold districts. The stems of all varieties are very slender and carry a very considerable armament of quite small hooked prickles. In the typical form the leaves

SOME DWARF RHODODENDRONS

FOR grouping in fairly open woodland, for the margins of shrubberies, the rock garden or mixed border, the Rhododendron family includes a large number of dwarf species and hybrids which are among the most precious shrubs we possess. The majority of them are hardy, and easy to grow to perfection in any lime-free loam in sun or half-shade with some shelter from wind. All that they require, where peat is absent, is a little leaf-mould or really old cow manure at the time of planting and later on as an occasional top-dressing. A cool root-run and one that does not dry out in spring or summer is highly desirable, for the fine, hair-like surface roots are very susceptible to drought. At the same time the drainage must be good, and while the soil is retentive it should be of a loose and friable vegetable nature.

Omitting, owing to the exigencies of space, the mollis, Ghent, rustica and Japanese groups, usually classed as Azaleas, there still remains a wide selection of dwarf species and hybrids of great beauty and interest, nor will the average gardener find many of them beyond his pocket. Moreover, as such plants as these are almost invariably sent out budded, and as they move better than most things, a display may be confidently expected the first season and this without detriment to the shrub. I need hardly add that many of the Rhododendrons mentioned below are often known as Azaleas.

Usually the earliest to bloom with us, *R. præcox* is also one of the most charming. A hybrid between *RR. ciliatum* and *dauricum* it is a neat-habited evergreen of 3ft. to 5ft., with deep green, glossy leaves and terminal trusses of pretty rose-purple flowers which often appear a clear shell-pink in the subdued light of January and February, when the shrub is frequently in full flower. An excellent variety for grouping in woodland or where it can be afforded some shelter from hoar frosts and biting winds, both of which are liable to injure the blossoms.

Of the two parents of *R. præcox*, *R. dauricum*, a January bloomer, does not appear to have a good reputation and it has not been tried here, but *ciliatum*, with its fresh green, hairy leaves and usually large flowers in a lively apple-blossom pink-and-white is reliable and good. This, however, also needs a sheltered corner, for the big blossoms, produced in spring in loose clusters, are apt to be broken by wind.

Another early bloomer is the beautiful Chinese *R. ledifolium*, also an evergreen, with dense, hairy foliage and close, shrubby habit. This fine species, which reminds one of the old *Azalea indica* of greenhouses, and of which it is probably a form, is perfectly hardy here, though a sharp March frost may prove mischievous with the breaking buds. It is, nevertheless, one well worth the risk of occasional disappointment, its milk-white trusses being indescribably lovely. The wise will give *R. ledifolium* a westerly exposure, and, if possible, the protection of some deciduous tree.

Perhaps the most weather-proof of all the smaller Rhododendrons is *R. (Rhodora) canadense*, a deciduous little shrublet and most faithful bloomer. It usually breaks its plum-coloured buds in March

or April and the slender twigs are soon bearing a veritable constellation of gay, rosy-purple flowers with long, protruding stamens. An easy doer in almost any moist soil. Before this pretty thing is over, and it remains in flower for several weeks, another *N. American*, *R. Vayesi*, opens its daintily crimped white flowers which are tastefully touched with pink. These flowers appear before the leaves, the species being deciduous. It is perfectly hardy, a reliable bloomer and, though it attains the stature of a small tree in its native soil, it is a very slow grower with us, making no more than 2ft. to 3ft. in many years.

R. racemosum is deservedly a favourite for it is extremely hardy and though it flowers in early April the blossoms (pale blush) are in such compact trusses that they rarely suffer from spring frosts or wind. This is an evergreen from some of the highest altitudes of China, with box-like leaves with wide underparts and a stature of about 4ft. There is a variety (*roseum*) with flowers of a deeper pink. The sturdy little Himalayan, *R. glaucum*, though not often seen, is worthy of wider popularity. It usually escapes the frost here, since it does not expand its rosy blooms until May is well in. The individual flowers, about 1in. across, short, bell-shaped and fragrant, are borne in corymbs of seven to ten. *R. glaucum* does not appear to grow to more than about 2ft. The leaves, which are comparatively large, are of dark, glossy green above and white beneath.

In the woodland there is something peculiarly attractive about *R. punctatum*. It is a low, spreading evergreen with smooth, dark green leaves and neat terminal trusses of bloom in a clear porcelain pink. Being a North American it is perfectly hardy and one that does very well with considerable shade. To *RR. punctatum* and *hirsutum* we are indebted for *R. myrtilifolium* which has inherited about an equal share of each parent's features. The foliage is rather smaller and more compact than in *punctatum* and the flowers considerably less in size and of a fuller pink or rosy red. This is also an easy-tempered bushling almost anywhere. But as much cannot be said of the *punctatum* × *ferrugineum* hybrid known as *R. arbutifolium*, or Wilson's Rhododendron. In our experience this delightful little evergreen, with pointed, glossy, pale green leaves, is everything that could be desired in one place and a disgruntled, dead-alive affair in another, even when the latter is, in our estimation, precisely like the other. The fact is, with us it inherits *ferrugineum*'s habit of dying-off piecemeal unless, as I have suggested, we can by chance hit upon a spot of which it approves. Our two best plants of *R. Wilsonae* are now thriving in soils and positions totally different from one another. The one is crowded in among a mass of *Erica ciliaris* and other Heaths where there is moisture and leaf mould in plenty, the other is isolated in the driest, poorest and hottest corner of our propagating garden, usually delegated to such "cast-offs" as may be "stuck-in" there to do or die as they please. Yet both plants are equally vigorous. But, despite its uncertainty, Wilson's Rhododendron remains one of the best of the dwarfs, one worth much patience.

RR. ferrugineum and *hirsutum*, both known by the name Alpine Rose, or Alpenrose, come from the higher elevations of the European Alps and are therefore perfectly hardy little rusty-leaved evergreens of about 18ins. the latter being the more hairy of the two. Both of them are apt to disappoint by dying-off in the manner described and neither of them flower so freely with us as *R. Wilsonae*. These species seem to nurse a longing for the atmosphere of their lofty native home, as do some other alpine plants, and I am not at all sure that they are good enough to merit much patience. *R. hirsutum* is one of the few members of the genus

which will do in limy soil and in this respect may be likened to that precious gem and most capricious of plantings, *R. (Rhodothamnus) Chamæcistus*, whose fatherland is the limestone of the Tyrol and whose "spiritual home" is somewhere in the disappointed hearts of a legion of English rock gardeners. This choice shrublet of a few inches has existed in a grudging sort of way, for some years in our garden but, though it puts forth shoots of hope every summer, they are like unto the "hopes that triumphed and fell dead," for they come to nought. Whether this fascinating infant wants lime or whether it detests it I dare not venture to decide in the face of the divergence of opinion that exists on that question; but this much may be said with certainty. It is not lime or the absence of lime which are the chief causes of failure with *R. Chamæcistus*.

With the approach of summer *R. viscosum* of the shady wood-bottoms of America adorns its leafless branches with fragrant white flowers, whose stickiness gives the species its specific title and the English name of "Clummy Azalea." This is a good-tempered, hardy little shrub in a suitably cool place and the same may be said of one of its off-shoots, *R. azaleoides* (*fragrans*) a semi-deciduous hybrid of 3ft. to 4ft., whose white, lilac-tinted blooms with the scent of Honeysuckle appear about the same time as those of the foregoing.

A good word must be said for the evergreen, *R. anemum*, even if its multitudes of tiny, vivid crimson flowers do strike a magenta hue in some lights, for it is very charming in itself and to it we owe much for a long list of lovely forms in shades of orange, salmon, flesh, scarlet and crimson. A. T. I.

A SELECTION OF SAXIFRAGES

(Continued from page 614.)

THE Tufted or Cushion Saxifrages—those belonging to the *Kabschia* group are among the choicest and most beautiful of rock garden plants. Most are early-flowering and some of them blossom at a season when what little other flower there is comes from small bulbous plants. Early January will often find *Saxifraga Burseriana* in flower. This is a very beautiful, if variable, species with pure white flowers on bright red stems a couple of inches tall. The foliage is very glaucous and spiny. Variety *major* has larger flowers and is usually a little later to flower than what is generally recognised as the type plant. Altogether larger in flower and foliage is the form called *Gloria*, which is a little later to flower, has very substantial blossoms, but very little colouring to the flower-stems, which is unfortunate, as the bright stems greatly enhance the appearance of the typical form. Rather shorter of stalk, another large-flowered form is called *magna*. Other distinct varieties are *macrantha*, about the last to flower, *tridentina* with wavy petals and *crenata*.

Saxifraga marginata is another magnificent early white-flowering species which bears its

flowers in small heads of five to seven. It usually flowers in March. The edges of the rosettes are encrusted with lime, hence the specific name. This is a particularly interesting and charming plant. *S. Boryi* is very similar but later to flower. *S. Rocheliana* is also similar but smaller. The foliage is even more noticeably encrusted and the flowers are borne fewer together, two or three being the usual numbers. Variety *coriophylla* has broader leaves and ivory white flowers, and there is also a yellow-flowered form which is still uncommon.

The golden yellow *Saxifraga sancta* is far less interesting in appearance owing to its deep green mossy foliage. It is, however, a useful, easy and free-flowering species; the small, rather cupped flowers are borne thickly together in heads. *Saxifraga Pseudo-sancta* is so similar, not only in appearance but in botanical characteristics, that it is hardly worthy of specific rank. It is later flowering. *S. juniperifolia* is less showy than either, but has in the eyes of some people the very considerable merit of being difficult to grow.

Another admirable yellow-flowered species is *S. Ferdinandi-Coburgi*. The foliage is slightly

A LOVELY FORM OF BURSER'S SAXIFRAGE, *S. BURSERIANA CRENATA*.

glaucous and the flowers are borne in heads four or five together. This is an easy and altogether desirable species, but it is not often obtainable true from nurseries.

Saxifraga cæsia is a tiny species with closely silvered leaves and creamy flowers clustered loosely together in heads of two or three. *S. aretioides* is a glaucous-foliated kind with yellow blossoms. There is a form larger in all parts and with primrose-coloured flowers known as *primulina*. *Saxifraga tombeanensis* is another silvery foliated species with white flowers. It is now considered to be only a form of *S. diapensioides*, a tiny species, also with silvery foliage, which bears disproportionately large flowers several together on, for the rosette, tall stems in April.

With *Saxifraga lilacina* we come to a species bearing rosy lilac flowers. These are borne singly on inch-long stalks, and the foliage is tiny but silvery. It is by no means free to flower.

The hybrids of these Kalschia *Saxifragas* are, on the whole, easier to grow than the parent species, and some of them are extraordinarily beautiful. It is doubtful, indeed, whether the average gardener realises how many of his favourites are, in fact, hybrids. Perhaps the best known of them all is *S. apiculata*, next to *S. Burseriana* perhaps the earliest to flower. Its primrose yellow flowers are borne three or four together, and are produced with remarkable freedom. The foliage is rich green, but by no means so dark as that of *S. sancta*, between which species and *S. Rocheliana* it is said to be a hybrid. There is a pure white sport from the typical plant in commerce which is equally desirable.

Saxifraga Burseriana crosses readily with *S. aretioides*, and there are at least two such hybrids in commerce. *S. Boydii* is very early-flowering and has fairly large deep yellow flowers. *S. Faldonside* has larger, better shaped flowers than the last but of softer colouring. It is a far easier plant to cultivate and rapidly grows into nice tufts. *S. Boydii alba* is unnamed. Though quite a good plant and an easy doer, it bears little resemblance to *S. Boydii*.

Saxifraga Cherry Frees is a hybrid between *S. Burseriana* and *S. sancta*. It differs only from *S. Elizabetha* in being a more vigorous grower with a better constitution. The rosettes are green, the flowers sulphur yellow and the stems tinged with red.

The plant known as *S. Irvingii* is said to be a cross between *S. Burseriana macrantha* and the English species *Frederici Augusti*. It features *Burseriana* habit, but has bright bluish-coloured blossoms. *S. bursiculata* is said to be the result of crossing *S. Burseriana* with *S. apiculata*. The flowers are white and substantial and of some size, and the flower-stems are stiffer than with *S. apiculata*. The foliage is slightly glaucous.

S. Haager represents the result of crossing *S. sancta* with *S. Ferdinandi-Coburg*. It is in the way of the last mentioned, and is an exceedingly easy and valuable plant. *S. Pauline* (*Burseriana minor*—*Ferdinandi-Coburg*) almost features the last-named species. The flowers, however, are pale yellow. This is an easy doer and very charming.

Saxifraga Petraschii (*tombeanensis*—*Rocheliana*) forms a very dwarf cushion of glaucous rosettes from which flower-stems spring freely bearing three or more large white blossoms on each head in March. This also is an easy plant to do and especially lovely under glass. *S. Solomonii* (*Burseriana*—*Rocheliana*) is a good doing plant which might be described as *S. Burseriana* with two or three flowers to each flower-stem.

THE PINKISH SAXIFRAGA IRVINGII.

ONE OF THE BEST OF THE HYBRIDS, SAXIFRAGA FALDONSIDE.

ADMIRABLE IN FLOWER AND FOLIAGE, *S. MARGINATA*.

THE GENUS ALONSOA

A very Useful Race of Hardy Annuals.

HAVE you ever got down a whole lot of cyclopedias, dictionaries of gardening, books about annuals and such like, and read in them about Alonsoas? I have just done it, and now I am wondering whether I am on my head or my heels. I did think I knew orange from scarlet and scarlet from orange, but now I doubt if I know black from white, and I see as I never saw before the force of W. S. Gilbert's famous couplet in "H.M.S. Pinafore":

"Things are seldom what they seem,
Skim milk masquerades as cream."

I have grown what I believe to be *Alonsoa acutifolia* in a fair-sized patch in the garden this year. I have observed it in shade and sun, in early morning and late in the evening, on Sunday and weekday, and it never entered my head to call it anything but orange, yet I look it up in "Speer's Annual and Biennial Garden Plants," and find under *acutifolia* "Scarlet flowers in June." I am very doubtful indeed about the June part of the description, and until I consulted Nicholson's Dictionary and found *linearis*, which is as like *acutifolia* in colour "as two peas," I would have been prepared with my bottom dollar to wager Speer was wrong about his colour. And then when I read on in this good man's book and come to jaw-breaking *Warszewiczii* where, to add insult to injury, I find it is said to have "small but dazzling orange-red flowers," I was just "done brown." In desperation I turned to that excellent little encyclopedia of Mr. Sanders. He is very brief. "*Linearis*, scarlet"; "*Warszewiczii*, scarlet." Speer, by the way, also calls *linearis* scarlet. Now let *Warszewiczii*, *linearis* and *acutifolia* be what colours they may, nothing is more certain than that they are not, as the unwary might be led to suppose, all alike. *Linearis* and *acutifolia*? Yes, but not the unpronounceable one. I have probably told the tale before, but it is so good it bears repeating. A friend of mine one summer gave an old lady in his village some plants, which she set and tended with great care. Later on in the year as he was passing he called and asked her which she liked best. "Oh! Mr. A, that beautiful red one, Alfonso Whiskey-and-Soda."

I have never grown *incisifolia* (unless as *Warszewiczii*), *linifolia*, *Mathewsii* or the white form of *acutifolia albiflora*, so I can say nothing about them from personal experience, but I have grown a very pretty pink variety *Mutisii* which I am unable to find in either Bailey's American Cyclopedic or in Nicholson's British Dictionary. It is noted, however, in Speer, where the flowers are described as chamois-rose. Personally, I would have called the usual typical colour a real pink, with no rosy inclination whatever. The rose touch is the exception, but when it is there *Mutisii* is a new creature, and can claim an equal share in the glory of the race with its old hard named rival. Miss Jekyll can never have seen the very latest out in *Mutisii* as we have it here at White-well or I feel confident she would not call *Warszewiczii* "the best of the several kinds of Alonsoa" in her book "Annuals and Biennials." Instead of one I put three in the front rank: *acutifolia*, a rich ruddy orange; *Mutisii*, a pink; and *Warszewiczii*, a real scarlet. They are all much of a muchness in their habit of growth, developing with age a multitude of long thin stems clothed at frequent intervals with narrow, saw-edged leaves and bearing flat, irregularly lobed blooms of any size between a sixpence and a shilling in

their upper region. The plants improve as the branching increases, and the sparse show of their youth is soon forgotten in the goodly multitude of flowers to be seen in their maturer age. A large clump in a herbaceous border or a big isolated bed on a lawn filled with them are the main purposes for which Nature has fitted them, but they make excellent and, at present, uncommon pot plants for a conservatory or very cool greenhouse if treated like *Schizanthuses* or *Clarkias*, from which families they are a welcome variation in their colour of flower and habit of growth. The easiest way to grow Alonsoas is to treat them as half-hardy annuals and raise them in heat in order to promote early flowering. In such a summer as the one we have just passed through it was very plain to see how advantageous it was. They take time as it were to get into their stride. I have sown them in the open where they are to flower, in April or early May with very fair success in a warm summer, and doubtless in more southern

and warmer parts of our island out of door sowing may be regarded as a quite safe and satisfactory proceeding. Pinching is not necessary except for pot plants. If the young plants are given plenty of room when they are put into their flowering quarters they naturally branch a good deal, and it is only when all these branches come into flower bearing that Alonsoas are at their best. The usual strains grow from 18 ins. to 2 ft. in height, but there are pigmy strains as well I am told, but I have never seen them. I am always very doubtful about "warts," as my old man John invariably called them. Some, like the pretty Cambridge blue *Nemesias*, are quite all right, but others are more fit for the manure heap than a bed or border, e.g., Cupid Sweet Peas. Alonsoas may be propagated by means of cuttings, but they come so readily from seed that I should doubt its ever being worth while doing unless it is desirable to increase some very special variety.

JOS. LPH. JACOB.

WINTER WOOD & SUMMER FOLIAGE

TREES as a rule display the beauty of their bark at all seasons of the year. Such are the Beech and the Birch, for instance. Even these, however, shew to greatest advantage their beauty of proportion from trunk to branch and so to branchlet and tiny twig when stripped of their

have another claim to consideration, resting on their picturesquely twisted growth. Most of the Willows are handsome in their winter dress—the Sallows because of their ever-developing male catkins and the Osiers because of their coloured woods, ranging as they do from greenish yellow to orange and crimson and again to

FLOWERS AND BRIGHT BLUE FRUITS OF *VIBURNUM DAVIDII*.

summer dress. Shrubs with beautiful bark display it, if at all, only in winter. Now few of us have space at disposal to devote a stretch of ground solely to winter effect. It is wise, therefore, to consider how to arrange the grouping so that winter effect may be obtained without detriment to summer beauty.

Let us, first of all, consider the trees and shrubs most valuable for winter effect. Of trees the Birch and Beech have already been mentioned, the latter too large and too greedy a feeder for the garden proper. In addition to these the Hazel must not be overlooked, for though it has no special beauty of colouring, its multiplicity of twiggy is effective—especially so when laden with hoar-frost. The Apple and the Judas Tree

the bloom strewn purple of *Salix daphnoides*. Among shrubs there is a great diversity of coloured wood ranging from the bright red bark of the Dogwood to the white of certain Brambles and the bright greens of the Broom family (both *Cytisus* and *Gemsta*) and of *Kerria* and *Leycesteria formosa*. The green arching canes of the latter to shew to best advantage must be freed from the older wood, which is brown and uninteresting. The current year's wood of the larger Mock Oranges, such as *Philadelphus coronarius* and *P. grandiflorus*, is at once interesting and warm looking in its bright paper brown. The wood of the smaller sorts is actually similar—so is that of the *Dentzias*—but on the smaller scale they are far less effective. The arching canes of the

Diervilla (Weigela) are also handsome in a similar way. The arching downy canes of the small-tollaged evergreen *Cotoneaster pannosa* are effective in winter, especially as they are wreathed at that season with rather dull red berries.

Further colouring is to be obtained if wanted by utilising evergreens which change colour in winter, such as the Mahonia, *Berberis Aquifolium* and the Wand Flower, *Galax aphylla*, on the one hand, or various kinds of *Arbor-Vitæ* (*Thuja*) and *Cryptomeria* on the other. The former class provide rich crimson and orange shades to an extent varying considerably with soil and season, the latter tones of russet brown, purple and maroon.

With such a wealth of material, remains only to use it to best advantage. The Moek Oranges,

Brooms and *Kerria* are readily utilised, since they are shrubs we should select for their blossom, even though they had no other merit, nor need the handsomely flowered and fruited Mahonia or the gorgeously berried Barberries present any greater difficulty than that of bearing them in mind when planning, but such things as the Dog-woods and *Leycesteria* need care if the summer effect is to be satisfactory. The common red *Cornus sanguinea* is, especially when cut to the ground each spring, as it should be to produce its maximum of winter effect, rather a coarse-looking plant for the shrubbery. This drawback may to great extent be overcome by employing the silver variegated form or the handsome golden form called *aurea Spathii*, though neither of these is quite so handsome of wood as the typical plant

obtain some dung for hot-beds, which were made use of in the way already described, and the second generation of cuttings grew like nettles. We had an abundance of good plants by the time they were wanted.

The Council of the Society were evidently satisfied with my work under difficulties, for I had the honour of receiving from them a handsome present.

WILLIAM TAYLOR.

RAPID METHODS OF PROPAGATION

WHILE cuttings emit roots without a change of air? During the fifties of the last century, when only seventeen years of age, I was responsible for the production of 100,000 bedding plants, having previously served under five different foremen in the same department. This was at Shrubland Park in Suffolk, made famous by the work and writing of Donald Beaton. Some of the routine then practised is a puzzle to me even now. Perhaps there is nothing extraordinary in what will be mentioned first, but more will follow which, to me, does not appear so simple.

In the first place, cuttings of such plants as Verbenas, Petunias, Heliotropes, *Tropæolums*, *Ageratum*, etc., were inserted in boxes, covered with glass, and made perfectly air-tight by pasting paper on the edges of the glass and the boxes. These were then placed in a position in the propagating or any other warm house during winter or early spring, where no direct sunlight could reach them and were not otherwise shaded. They remained till there was a sign that the formation of roots had commenced. Then a slit was made in the paper all round, and after another day or two the glass was slid away from one end about a quarter of an inch, and this was done in the evening. When another day or two had passed the glass was removed altogether. This was also done in the evening after the house was closed. I had previously been taught by my several foremen, who included Scotch, English and German, that the glass must be lifted and made dry, or turned every morning. This is not necessary if the cuttings are placed where the fluctuations of temperature are only slight, as on the floor of the house. Very little moisture will then arise.

The cuttings of plants already named are not long in emitting roots, so there is nothing marvellous so far; but I went a step further and tried the same plan with Perpetual Carnations, Tea Roses, Gardenias, etc., and it succeeded admirably. Roses were from plants grown indoors, with the wood partly hardened, say, just forming a flower-bud. Carnations were mostly slips from flowering stems. If inserted in February, these would remain without ventilation three weeks or sometimes a little longer. If they were kept closely covered a day or two too late, the result would not be satisfactory, but attended to at the proper moment not a leaf would be lost.

When cuttings other than my own, and where perhaps the plants had not been growing so freely, were used, the results were not so good. When there is visible growth before a callus is formed there is very little chance of success.

Another plan with Verbenas, which were then very popular, and of which perhaps twenty

thousand would be required, was to make an old-fashioned hot-bed (many modern gardeners scarcely know what this is), place a frame on it, insert the cuttings in boxes, and keep them in full sunlight as late as the end of April. The steam rising from the fermenting material, in the condition old gardeners called sweet, would afford sufficient shade and roots would be formed in about forty-eight hours. I could not say what the maximum temperature would be, but certainly 120° or more, and they were kept perfectly close till growth commenced. If a light had been opened during the middle of a bright day, the cuttings would immediately have collapsed.

I found that Verbenas need not be cut to a joint, which, of course, makes a great difference in the time required for the operation and the quantity produced, which are considerations when many thousands are wanted. There are many other soft cuttings which could be rooted in the way I have mentioned on the unshaded hot-bed, supposing that stable manure can be obtained.

I practised the same express system of propagating Verbenas and *Tropæolums* at Chiswick in the spring of 1861, when I was responsible for the production of plants to furnish the beds at the R.H.S. gardens at Kensington, which were opened on June 10 in that year.

The summer (?) of 1860 was the wettest and coldest I have ever known. Stock plants grew very little, but insects, especially thrips, flourished amazingly, and I did not know so much about killing them as I do now. There was a trial of Verbenas of all known varieties, but they were a complete failure. To complicate matters, there was, on Christmas Eve, 34° of frost, and the boiler of the house containing my principal collection of bedding plants, including *Geraniums*, gave way; but, thanks to my dear old friend Barron, who was then general foreman, not a plant was lost. The house was covered early in the morning with thick canvas, and when the temperature rose to about 30° the plants were freely syringed with cold water. Fortunately, there was sufficient sun-heat to raise the temperature of the house above the freezing point and not too rapidly.

Many trees of *Cedrus Deodora* soft, high, in Glendenning's nursery at Turnham Green, were killed outright. The winter of 1858-59 was quite as severe and these trees escaped, but that came after a hot summer, the summer of Donati's comet, a never to be forgotten sight.

When March, 1861, arrived, the Verbenas, especially Purple King, which was wanted in quantity, were a sorry spectacle, and Mr. Eyles, the superintendent, was afraid we should have nothing worth planting out. I persuaded him to

A WHITE BUTTERCUP

THE plant of which I wish to write is generally catalogued and grown in nurseries and gardens as *Ranunculus rutæfolius*. It takes people a long time to adopt some of the authoritative names for plants which we have known for a long time by names now superseded by botanists, although still in use in gardens. In the case of this plant too, the proper title of *Callianthemum coriandrifolium* or *C. rutæfolium*, is more cumbersome and difficult for the many. Whatever name the reader may choose to adopt, the plant itself is not unworthy of cultivation in the rock garden. The late Mr. Reginald Farrer had but a small opinion of this flower, but I do not think that he could have known it well under the best garden conditions or he would probably have modified his verdict to some extent. The concluding paragraph of his reference is more kindly, however, than his previous remarks, founded upon the plant in its native habitats, where it is undoubtedly coarse. It must be admitted that it is not the best of the *Callianthemums*, but it is worthy of consideration. In the poor, stony, gritty, sandy soil which seems to bring out its attractions much better than a rich one, it is a neat, low-growing, rather trailing plant with fine fern-like foliage, giving rise, I suppose, to its specific names of *C. coriandrifolium* and *Ranunculus rutæfolius*, resembling as it does that of the *Coriander* or some of the *Meadow Rue*s. From this tuft of leaves, only 3 ins. or 4 ins. high, in poor soil, are produced trailing stems bearing fairly large daisy-formed blooms with narrow ray-florets of dull white and with a greenish centre. It reminds one, so far as its blooms go, of those of *Pyrethrum uliginosum*, but not quite so white in their rays. It is not a flower which will bring forth ecstatic remarks from the many, but it is one which has many points of charm when treated as it should be. Regarding its treatment we may at once abandon the idea of cultivating it in rich soil, such as it generally has at home, where it often grows among the turf, with plenty of moisture beneath. I have never found it so satisfactory as on a flat terrace of the rock garden, a little above the ordinary ground level, fully exposed to the south sun, and growing in loam with plenty of sea-sand, grit, and stones, and firmly planted. In such a compost and with the ample drainage the plant likes, we can keep it dwarf and neat; but under such conditions it may suffer from drought in spring and summer when it is coming into blossom or even when in flower, and it is desirable to water it freely and pretty frequently with pure water at that time. With such treatment it will surprise those who only know the *Callianthemum* in rich soil, where it looks comparatively coarse and unattractive. It is not an easy plant to propagate, indeed, it is risky to divide it, even in the case of fair-sized plants. It can be divided successfully and an examination of its roots would suggest that it might be increased by root cuttings. I have not been successful with these, however, and I do not think the roots respond to this practice. Seeds are the best means of propagation, but are not easily obtained.

S. ARNOLD.

CORRESPONDENCE

THE TWELVE BEST SHRUBS.

I ENCLOSE two lists, each of a dozen shrubs.

The shrubs on the first list are for an everyday soil and climate, and on the second for a warmer and more peaty soil. I have grown all that are mentioned in ordinary soil, but lost several during the very hard winter we had some years ago. I have also grown all the twelve in the second list in Ireland and they grow there much better in practically nothing but peat.

I have not included Rhododendrons, Azaleas, Roses or climbers, as they are classes by themselves and one could easily get twelve out of any one of them.

The trees in the lists are *Fremontia californica* and *Magnolia stellata*, but both of them flower just as well as shrubs. I have *Fremontia californica* on a 5ft. wall well pruned back and it flowers freely every year. *Magnolia stellata* flowers when 2ft. or 3ft. high and spreads shrub-like and is easily kept as a shrub.

Perhaps a Scotch reader would oblige with the names of a dozen selected shrubs, hardy in the colder parts of Southern Scotland and not near the sea. Hardy there, they would be hardy anywhere in England. It would be well to get a list of good shrubs hardy anywhere in England.

List I.—*Forsythia suspensa*, *Eucryphia pinnatifolia*, *Philadelphus Virginal*, *Ceanothus Gloire de Versailles*, *Magnolia stellata*, *Berberis stenophylla*, *Buddleia variabilis Veitchiana*, *Cydonia japonica cardinalis*, *Daphne Mezereum*, *Syringa* (Lilac) *Mine*, *Lemoine*, *Spiraea Eumalda* Anthony Waterer, *Exochorda grandiflora*.

List II.—*Embothrium coccineum*, *Magnolia stellata*, *Trienspidaria lanceolata*, *Zenobia pulverulenta*, *Kalmia latifolia*, *Eucryphia pinnatifolia*, *Fremontia californica*, *Buddleia variabilis Veitchiana*, *Cistus ladaniferus*, *Clethra alnifolia*, *Romneya Coulteri*, *Desfontainea spinosa*.—J. D. C.

FROM CHILI.

A FEW weeks ago (November 23 to be precise), that beautiful shrub, *Desfontainea spinosa*, was a blaze of colour, the gorgeous tubular flowers in a bold crimson-scarlet and yellow being as large and as numerous as they were in July; but *D. spinosa* had overstepped its mark, for on the night of the above date there came a white frost (6°) which turned every blossom to ashes. It must not, however, be assumed that this handsome shrub is peculiarly susceptible to frost. We have grown it for at least fifteen years and never once have its holly-like leaves suffered the slightest injury. It even came scathless through the terrible ordeal of early 1917. Among the best of the many good things we have had from Chili, *D. spinosa* is a shrub not to be overlooked by anyone whose climate is not very bleak. Perhaps one would not be far wrong in saying that it might be planted with confidence in any locality in which *Berberis Darwinii*, another Chilean, succeeds.—A. T. J., *N. Wales*.

A BEAUTIFUL WEEPING ELM.

WHILE reading the informative article on "Pendulous or Weeping Trees," by "A. O.," on page 579, I was expecting mention of *Ulmus montana pendula* Camperdowni. The tree is better known than its name, for I have noted a considerable number in various gardens and in different counties during the past twenty years, but only in one nursery, and think that others must be distributing this beautiful tree, considering the wide area over which it is now distributed between its original home, Camperdown House, near Dundee, and Cornwall. I was recently shown

a specimen from the latter county and was asked for its name. The tree is much smaller or more compact than the much older *U. m. pendula*, with a regular and umbrella-shaped head. The leaves, on the other hand, are very much broader than those of the older weeping variety, and they completely cover the branches of the tree while it is in leaf, whereas the leaves of *U. montana pendula* are directed below most of the branches, leaving the latter exposed to view. The trees of the Camperdown Weeping Elm that I have seen are sometimes planted in gardens, occasionally in courtyards, and in one case a tree was planted on either side of the front garden gate. A little trimming was given to keep the gateway clear,

TROPAEOLUM POLYPHYLLUM AT NEW PLACE, LINGFIELD.

but otherwise these small weeping trees gave no trouble. The great spreading arms of *U. m. pendula* require more room.—J. F.

TWO PERENNIAL TROPAEOLUMS.

I HAVE noticed several references to *Tropaeolum polyphyllum* and *speciosum* in THE GARDEN during the past season, and there are doubtless many who are desirous of growing them who have met with failures in the past. As regards *T. polyphyllum*, most failures to establish it have been caused by shallow planting. The roots should be not less than a foot deep in stiff soils, and in lighter soils and well drained positions they should be quite 18ins. down. In an old-established bed they range themselves from 1ft. to nearly 3ft. in depth. We have here a narrow border of about 60ft. in length where it has been established for several years. The subsoil is clay, and I have followed the roots down to 2ft. 6ins. in depth. This is not a good position for it, as it flowers in June and dies back at the end of the month, leaving an awkward blank which needs a good number of plants to be kept on hand to give another display. In former years, when bedding-out was not favoured here, we

planted thickly with the hardy *Gladioli*, and for an autumn display sowed Candytuft, thus keeping the border bright over a long period. In 1919 an attempt was made to eradicate the *Tropaeolum*, but this proved impossible owing to the many roots of climbers in the border. By 1921 the few roots left had again monopolised the border, and I enclose a photograph of part of the border taken last June shewing the great mass of bloom. This should encourage those who have hitherto looked upon it as a difficult plant to grow. *T. speciosum* is a much more difficult species here in the South, but I feel sure there are many gardens where it might be tried with a fair chance of success if its special requirements are given due consideration, and disturbance after planting, its especial abomination, avoided. Like many of the Lilies, it loves to have its heels in shade and its head in

full light. This species is a shallow rooter, and the long, fleshy roots are very brittle. Here it thrives best in peat under the shade of tall Rhododendrons and under other shrubs with plenty of decayed leaf-mould near the surface. Lime, as mentioned by one correspondent, appears quite unnecessary, as our soil is quite free from it. Why I think it could be more generally grown in Southern gardens is the fact that it has existed for years in every possible position here. Pieces of it are to be found all over the place among shrubs, herbaceous plants and in the kitchen garden borders under bush Apple trees, but the digging in the borders breaks up the roots into too small pieces to store sufficient food to enable it to throw up a strong flowering stem. The best display is given when growths of the previous season come through a very mild winter unharmed, which has occasionally happened here. Those who try it must not be too impatient for results, but allow it time to form strong roots. Seeds are, naturally, slower than roots and need special treatment. Drying kills them, therefore they must be sown as soon as ripe or stored in soil constantly kept moist for a year, as they require this time before germination takes place.—H. C. WOOD, *New Place Gardens, Lingfield*.

MICHAELMAS DAISIES.

FOR many years past two varieties of *Asters* have been known for their late blooming, viz., *Aster grandiflorus* and *A. Tridacanti*. During 1921 Mr. Amos Perry of Enfield marked a seedling which flowered later than is usual in the *Novi-Belgii* type, and this year is flowering equally late. Flowers were marked as opened on September 16, and to-day (December 2) perfect flowers may be gathered in perfect shape. This new seedling has been named *Winter Gem*. The flowers are a little larger than a shilling, pure white, with conspicuous yellow disc, and from 2½ ft. to 3½ ft. tall, with perfectly upright rigid stems and free branching habit. As a late-blooming border plant it will prove invaluable.—W. L.

CHRYSANTHEMUMS AND WINTER ROSES.

IN the account of the Autumn Show in Paris I was disappointed to see how little mention was made of the more artistic treatment of the flowers than is commonly seen in England. The quality of the cut blooms is higher in England, I think, at Chrysanthemum shows, but we can learn something from the French methods of arrangement. Not being a Chrysanthemum grower myself I do not venture to name what are the finest varieties, but there is one Japanese variety called *Tokyo*, with tubular petals and pretty pink colouring that entirely won my admiration, whether as a big cut bloom or a dwarf, cut-back pot plant with smaller flowers. I shall hope never to be without it and add it to the list of half a dozen or so that are indispensable. Continued fine sunny weather and a steady moderate temperature has produced the best crop of autumn or winter Roses I have yet seen. The Roses that have opened in a steady temperature between 65 and 45 have a perfection of petal that is striking, and the time that individual flowers last at this season is another great charm. The fierce suns and summer heats have their drawbacks in this climate. The winter-flowering *Gladioli* are now common objects on the flower stalls in the market, but they need some improvement yet in the size of the flowers and their disposition on the spikes; still, with late Chrysanthemums, their big sheaves of flowers make a very good effect. That cruel wind frost of two years ago has left its mark, and the beautiful *Acacia podalyriifolia* and the truly regal *Dahlia imperialis* are but rarely seen, so few survived that night. We now look forward to the stately *Montanoa bipinnatifida* to grace our Christmas garden. E. H. WOODALL.

PEAR TREES FOR ORNAMENT.

GARDEN lovers generally look forward to the great wealth of colouring in leaf and fruit which characterises many trees and shrubs during the autumn months. I should like to call attention to the varied and beautiful colourings of the leaves of some varieties of Pear. It was suggested recently in *THE GARDEN* (page 541) that fruit trees be pressed into service "to help the garden picture." Referring to Pear trees, the writer suggested that varieties of vigorous habit, such as *Catillac* or *Pitmasdon Duchess*, be used. He went on to give a list (on page 542) of those varieties with which he had had some success as standard trees on a light and warm soil. This list included, in addition to the two sorts mentioned above, *Williams' Bon Chrétien*, *Largouelle*, *Beurre Diel*, *Petite Marguerite*, *Conference* and *Dun-bleau*. These varieties, while serving as a guide, might be compared with those which have been found to be most reliable for the production of autumn tints when the trees are grown

in heavy soil. As a result of a number of observations upon bush-trained trees growing in such a soil it was found that the following seven varieties were most dependable in giving good coloured foliage, viz., *Triomphe de Vienne*, *Beurré Capiaumont*, *Beurré Jean van Geert*, *Souvenir du Congrès*, *Fertilité*, *Colmar d'Été* and *Durondeau*.—ROBERT H. JIFFERS.

AN ADVANCE IN SWEET PEAS.

WONDERFUL, of which I send a picture, is one of the best of the Sweet Pea novelties. It is bright scarlet-cerise, a shade deeper than *Royal Scot*, and like this variety, absolutely sunproof, in fact, the more sunshine it receives the better is the colour. There is this difference, however,

SWEET PEA WONDERFUL.

between the two varieties; the buds of *Royal Scot* are lighter and do not develop the true, rich colour in unfavourable weather or if opened in water, while with *Wonderful* the blossoms are scarlet, even in the bud stage. This is a decided advantage in a sunless season such as the past one has been or if the flower spikes are cut in a partly opened condition. I grew twenty plants of this variety for trial during the past season. It lacks nothing in vigour and gives a good proportion of four bloomed sprays, while during the few sunny periods which it enjoyed its brilliant colour was very telling. The long rows that were growing for seed were in full bloom when I visited Essex in late June, and they presented a wonderful sight. It is also as useful as *Royal Scot* for greenhouse culture, so is a recommendable novelty for all purposes.—N. L.

A NEW RACE OF CHRYSANTHEMUMS.

IN Mr. Edward H. Woodall's interesting letter on page 572, under the above heading, he refers to Messrs. Vilmorin's exhibit at the Paris Autumn Show last year of some very dwarf single Japanese Chrysanthemums. He recommends English gardeners to go there this year and satisfy themselves as to their worth. It is not certain whether Mr. Woodall saw these varieties himself last year or whether he is speaking from the photographs of them, but at any rate last year several of us English Chrysanthemum men were at the Paris Show and I have been also there again this year. Messrs. Vilmorin's exhibit is usually a colossal advertisement, whether they show in Paris or elsewhere. It contains named specimen plants of Chrysanthemums of many forms and sizes. It includes a variety of pot plants, one in particular a little brassy yellow Pompon called *Gerbe d'Or* they have used as an edging for many years.

Another family of dwarf decorative pot plants, always well represented at the French shows, is what we call the "Cap" family, but which is known to French growers as the *Baronne de Vinols* family, for there are probably twelve or fifteen sports from the parent or later issue. *Blanche Poitevine*, the name of which is persistently mangled by English growers in spite of all protests, is another valuable dwarf decorative Jap much in demand. This year while in the Paris Show I was accosted by a Channel Island enthusiast who had periodically come there to see what the variety, of which he had heard a good deal, was like. We found it in the Vilmorin group—and he was content.

But the "very dwarf single Japanese" referred to by Mr. Woodall puzzle me. He is not very explicit and although my experienced eye of forty years acquaintance with the Chrysanthemum at home and abroad is quick to detect any-

thing new or striking at a Chrysanthemum show, I cannot quite make sure what is meant. Last year at the Paris Show, which was also held in the *Palmarium* of the *Jardin d'Acclimatation* there was rather a pretty display of a lot of free-flowering small single Chrysanthemums arranged on each side of the steps leading to the great hall where the Vilmorin exhibit was then set up. These flowers very gracefully covered the two large pieces of artificial rockwork that adorn that end of the *Palmarium*. There were two well known English Chrysanthemum experts with me then, Mr. H. J. Jones and Mr. Thos. Stevenson, but I do not think any one of us was very much smitten with these novelties. Perhaps it was because we are all big-bloom men. This race is indeed a new one. I doubt if it will ever find much favour here—but that, of course, depends—floral fashions vary. The

popularity of some of the decorative Dahlia rubbish is ample proof of that. These new singles were raised by, or at any rate, sent from Japan, a few years ago by M. Foukouba, the gardener to the Emperor of Japan. My friend, M. Philippe Rivoire, grew and distributed them. They are very likely to please the French taste, but whether they will please ours remains to be seen.—C. HARMAN PAYNE.

ROSE RAISERS PLEASE NOTE !

THE season is quite as irregular in Rome as it appears to have been in England. After a drought lasting from April 25 until August 30, with great heat—104°—and hot winds, it rained somewhat more than usual in September and October. On September 28 I gathered a good bunch of Violets, and by October 15 one could find Violets,

Paper White Narcissi, Dahlias, Chrysanthemums, Apple and Pear blossom in quantity, Wallflowers, Cosmos, Orange blossom and, of course, very fine Roses. There is to be a municipal rose garden in Rome at Villa Borghese, and many of the big French rose-growers have promised to send plants. Perhaps some English or Irish rose-growers would also care to do so. They should be sent by parcel post to avoid a very long journey, addressed to the Director of Public Parks, Cav. Nicodemo Severi, Casino Dell' Orologio, Villa Borghese, Rome. He is the president of the newly formed horticultural society in Rome, which has just held a large and successful show. Rose-growing is somewhat backward here, but the new rose garden will probably change this and shew people what an excellent flower it is for this uncertain climate.—A ROMAN READER.

with the species that is found on Apple trees there does not seem to be an absolute certainty about the matter one way or the other. Anyway, if a badly infested Hawthorn hedge is near your orchard, it would be worth while to keep an eye on it as well as on the trees.

Mussel scale is found chiefly on trees that have been allowed to get their barks encrusted with

APPLE BLOSSOM WEEVIL.
(Greatly enlarged)

Passes the winter in the adult form.

APPLE TREE PESTS IN WINTER

WITHOUT some knowledge of the life-history of these pests it is impossible to treat the trees properly. Consider, for instance, the very common pests such as woolly aphis (American blight), the apple blossom weevil, the apple sucker, the small ermine moth

rubbish in and around the orchard must be burnt; hedge bottoms must be thoroughly cleaned out, also ditches; moss and lichen on tree trunks must be removed, as well as all loose pieces of bark, under which the weevils like to hibernate. A winter wash and, later, a lime wash will destroy numbers. Tits are certainly useful, and should

be encouraged to feed in the orchard; whatever may be said against them during the fruiting season, their services are undoubtedly valuable in winter.

The apple sucker lays its eggs at the end of the summer and dies. These eggs do not hatch out till March, and therefore between that time and the previous November, when egg-laying stops, endeavours should be made to destroy them. Paraffin emulsion is useful, both at the beginning and at the end of winter; also a lime-wash that will coat the twigs and prevent the hatching of the eggs should be applied just before the

lichens and moss. Trees with clean trunks are not often attacked. Winter is the best time to start measures of control, and in cases of bad attacks the trees should be occasionally sprayed from November onwards into February. Woburn wash or a home-made oil emulsion will answer all purposes satisfactorily if spraying is done thoroughly. For a few trees only it is best to buy an oil that will form an emulsion with water; there are various oils of this description on the market. To make 10 gallons of wash use 1 gallon of paraffin and nearly 2lb. of soft soap. The history of the mussel scale that attacks Apple trees is, briefly, as follows: The wingless nites are hatched about May. For a few days they walk about exploring the tree on which they find themselves; after that they choose a feeding-spot and fasten themselves to it by inserting their "trunks" into the bark. Having once accomplished this they never move again; apparently they lose the power of moving and henceforward they live for eating or, rather, sucking. Each insect begins to form a sort of covering, and this grows into the well known mussel scale. Towards the end of the summer they mature,

WOOLLY APHIS AND SEVERAL MUSSEL SCALES.

and the mussel scale; all these carry the race over the winter months in different ways, and therefore the same remedy will not always apply in more than one case.

The woolly aphis seems to be gradually solving the problem of dispensing with the male form and, therefore, also with eggs. The principal form is the wingless, viviparous female, which goes through the winter hiding in cracks in the bark or else travels down to the roots and hibernates there. To destroy these insects, which produce the numerous summer broods, a very efficient winter wash is needed, either a Woburn wash or a home-made alkaline wash made up of 2½lb. of caustic soda to 10 gallons of water. The bluish white "cottonwool" is seen on badly infested trees all winter, and this is, of course, a proof of the presence of the insects. The "cottonwool" exudes in long threads from the backs of the insects, both young ones and adults.

The apple blossom weevil passes the winter as an adult insect and is extremely difficult to find. The remedy here is an indirect one. All

buds begin to swell. The lime-wash is made with 15lb. of lime (best quick, in lumps) to 10 gallons of water, and spraying may be done to within about a week of the opening of the buds. This spraying must be done rather late, or it may be washed off by rain and the eggs exposed as before. Where the apple suckers are numerous it is better to run the risk of spoiling some of the leaf and fruit buds in order to make a thorough clearance of the pests.

In the case of the small ermine moths it is no use waiting till the larvæ are doing their worst, in July, before steps are taken to eradicate them. All sorts of winter washes are useful in getting rid of the tiny caterpillars which are hibernating on the twigs and bark. It is not easy to kill them, as they are exceedingly well protected. The eggs are laid about August in compact masses, each egg being firmly fixed to the next, and the larvæ, when they hatch out the following month, take shelter under the egg-roof, not coming out to feed till spring. It should be remembered that there is a species of small ermine that attacks hawthorn, and it is possible that it is identical

SMALL ERMINE MOTH.

The eggs are on the trees all the winter.

lay their eggs—about eighty to each insect—and die. The eggs are safe under the scale and remain there all the winter. It may readily be understood that a very thorough application of the winter wash is necessary in order to reach the eggs. Pears and Currant bushes may be infested if they grow near the Apple trees, as the insects are liable in the first few days of their life to be blown off the trees and carried elsewhere.

M. H. CRAWFORD.

H. J. ELWES, F.R.S.

BY the death of Henry Elwes a famous personality passes out of the horticultural world. For the past year or more his health had given his friends cause for anxiety, and when, a few months ago, he ceased his regular visits to London, it was evident the end was in sight. Of vigorous constitution, Elwes had hardly known a day's illness in his life until, a few years ago, he underwent a serious operation, from which he recovered in wonderful fashion.

Elwes never spared himself and, finding the call of the world irresistible, was continually on the move. His journeys were not undertaken in the pursuit of pleasure, but for some definite object, such as the quest of animals, birds, butterflies, plants, trees and shrubs, of all of which he was a keen student and an insatiable though discriminating collector. The search for these took him to almost every habitable part of the globe, and at times when travelling in foreign countries was not the comparatively simple business it has since become. Elwes was one of the first Europeans to enter Tibet, and before he went there he had made his way into Sikkim, a country which is still virgin ground to all but a few white men. While there he was vouchsafed a sight given to but few mortals—the destruction of an area of sub-tropical vegetation by an avalanche.

Like all great travellers, Elwes was a born *shikari*, and wherever he went was soon on friendly terms with the natives; even the Ainu took to him. His handsome, commanding presence, resounding voice, tireless energy and ready grasp of languages, no doubt contributed to this faculty, to which he owes much of his success as an explorer. As in the case of so many men, Elwes found the call of plants and trees irresistible, and for more than thirty years past he had devoted himself to both with unflagging zeal. The foundation of his interest in plants was laid in 1880, when, still in the thirties, he was so attracted to the study of Lilies that he published a critical monograph on the genus, and did it so well that, though now out of date, the book remains the standard work of reference on so much of the subject as it covers. Forty years later found him planning a supplement to the book. Like all true gardeners, Elwes had a catholic taste, and at one time or another every hardy plant worth growing, as well as a host of tropical and tender species, must have passed through his hands. Apart from Lilies, he was an authority on Fritillaries, Pæonies, Cinnam and Nerines, as well as Yucca, while his houses were crammed with tropical and sub-tropical bulbous plants. He often said that of all plants, monocotyledons attracted him most.

Elwes had a *flair* for good plants and a characteristic impatience of garden trash; but he was too restless, too much occupied with affairs and too much hampered by the inhospitable climate and *terrain* of his garden on the cold oolitic limestone of the Cotswolds, to be a great cultivator. Consequently his judgments on plants were not unerring; but, by personal visits he knew almost every garden worth knowing in Great Britain and Ireland and so was often able, as he was quick, to adjust erroneous impressions derived from his own cultural experience. In his horticultural work Elwes had the inestimable advantage, usually denied to gardeners, of personal observation of many species in the countries of their origin, and he probably saw more of the flora of the world than any amateur of his day. He never returned from a journey abroad empty handed, and horticulture is indebted to him for the introduction of many fine species.

Long after his forceful personality has been forgotten, Elwes' name will be gratefully remembered for his *magnum opus*, "The Trees of Great Britain and Ireland." This entirely satisfying work, in the preparation of which he had the felicitous collaboration of Dr. Augustine Henry, contains all that anyone—amateur or scientist—needs to know about our trees. In the closing year of his life he initiated the movement which resulted in the recent resurrection of the *Botanical Magazine*.

Of cultured mind and, to those who knew him intimately, of singular and attractive character, Elwes was accustomed to take a broad view of life, and his natural impatience of the restraints convention imposes on individuals and committees, showed itself sometimes in a momentary superficial *brusquerie*, of which he was unconscious; but his only object was the advancement of the cause for which he was working. An occasional tendency to allow personal prejudices to warp his judgment was balanced by a generous reversal of such judgment directly it was shown to be mistaken. [G.]

SIR I. BAYLEY BALFOUR, F.R.S.

TO both botany and horticulture the passing of Sir I. Balfour is an irreparable loss, for although he had recently retired from the official posts he had held so long and so worthily at Edinburgh, there was still much for him to do. While living, too, he was a perennial source of inspiration and encouragement to others—a priceless virtue—and there is no one to take his place.

Sir Isaac was both receptive and responsive to a degree, and it was those qualities combined with his practical knowledge, and, above all, the unselfish way in which he placed that knowledge at the service of others, even complete strangers, which attracted to him gradually all that was best in the world of botany and horticulture in our islands, as well as much that lies beyond them. A genuine interest in plants was passport to his friendship, and once admitted, contact brought continual refreshment to the eye and the mind.

Sir I. Balfour's point of view was that of the pure scientist, yet he always wore a pair of very human spectacles, and therein in great measure, lay the secret of his success. He covered the whole range of scientific botany as well as practical horticulture, and took as deep an interest, shall we say, in the hairs on the ovary of a minute *Primula* from some Tibetan mountain, as in the proportion of grit he thought the same plant would need in its pocket on the Edinburgh Rock Garden.

In the last few years of office Sir I. Balfour worked at greater pressure even than in the days of his prime; he burned both ends of the candle and did it solely for the advancement of science and horticulture. His position as head of a great national garden, to which a multitude of newly discovered plants came for cultivation, enabled him to distribute innumerable species, which, in ordinary way, would not have reached the hands of amateurs in general until after a long period of waiting. He used his powers wisely, generously, and to the immense advantage of practical horticulture. In his writings, as in his lectures, Sir I. Balfour was profound, but never prolix. The precious gift of clarity of expression was strongly developed in him, and he exercised it to such purpose as to infuse life into the dried leaves and withered flowers of some herbarium specimen from the other side of the world. His Master's lecture, "Some Problems of Propagation," should be in the hands of every gardener who propagates his own plants; while his enumerations of the newer

Gentians, the genus *Nomocharis*, *Primula* and above all *Rhododendron*, are classical.

Sir I. Balfour was appointed to Edinburgh in 1888, going thence from Oxford University, where he had occupied the Sherardian Chair of Botany for a few years. In the thirty-four years which have elapsed since then he has practically re-made the Garden—one of the oldest in the world. As we see it to-day, the Garden is a monument to the untiring devotion and wise administration of a man whose name must always be held in high honour in the realms of botany and horticulture.

[G.]

Gardening of the Week

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Early Potatoes.—As soon as the selected tubers are sufficiently sprouted planting may be commenced. The best results are obtained when a heated pit with a southern aspect can be made use of. Early Potatoes grown thus appreciate a little bottom heat and there is nothing better for providing this than a good bed of oak and beech leaves. Place about a foot of light, fairly rich soil on the bed and plant the tubers 16ins. to 18ins. apart from row to row, allowing 10ins. between the sets. Failing such a structure as mentioned, good results may be obtained from pots, or from narrow borders in cool houses, or even by erecting temporary quarters on staging, so long as plenty of light and air can reach them.

Parsnips.—Unless the site occupied by this crop is wanted early in the New Year, the roots are better left in the ground, for the flavour is undoubtedly improved after being seasoned with frost, etc. To make sure of sufficient available roots should a frosty spell be experienced, cover a portion of the bed with litter or leaves and there will then be no difficulty in lifting the roots when required.

The Hardy Fruit Garden.

The Fruit Room requires an occasional looking over for the removal of all decaying fruits, which, if left, will soon contaminate others. It may often be arranged that kitchen Apples, even though a little unsound, can be used immediately, and it is a good plan when overhauling quantities of late cookers to place all with slight blemishes together. Keep the room cool and maintain the atmosphere in as even a state as possible.

Raspberries.—Established plantations should be cleared of any unnecessary canes and have the remainder made secure to their supports, if the work has not already been done. Having finished tying, etc., clear the bed of any weeds, then lightly prick up the surface of the soil, mulching the old stools at the same time. Newly planted canes should also be mulched, but not cut down until February. Provided the soil is in workable condition it is not too late to plant, but if unfavourable weather intervenes, postpone planting until February. When making a selection of sorts, some canes of the perpetual variety Lloyd George should be included, and this, being a strong doer, should be given more room than other varieties.

Fruits Under Glass.

Tomatoes. Winter fruiting plants require an even temperature of about 56 to 60 at night, according to the outside conditions, and about 10 higher during the day. Maintain a buoyant atmosphere with the aid of a little air whenever the climatic conditions are favourable, and avoid atmospheric moisture entirely. The only moisture necessary in the house is that given to meet the plant's requirements. Always err on the side of shortage, if at all. Should a batch of young plants have been raised from an early November sowing they should be kept growing on a shelf well up to the glass in a temperature which does not fall below 55 at night.

Cucumbers. We are passing through the worst few weeks of the year for successful cucumber growing, and everything possible should be done to assist the plants carrying fruits. An occasional light rich top-dressing is always beneficial and should be regularly applied. See that all the light possible reaches the plants by having the outside of the house washed occasionally to free it from fog dirt, etc. Keep the roots of the plants in an even state of moisture and let the air be always a little moist. The temperature may run between 65° and 75 for day and night.

PERENNIAL PLANTS FROM SEED

UNQUESTIONABLY the average amateur does too little seedling raising. Admittedly there are some plants which it is quite unprofitable to raise from seed—many shrubs, for instance, which may be readily increased from cuttings and of which a comparatively few plants are required. Yet even here the traveller who leaves the beaten track is the one who makes discoveries. Only the other day your Editor had the controversy about the colouring of *Rosa Moyesii* explained to him. This extraordinary and handsome Rose refuses, it seems, to come true from seed, indeed, seedlings from what we have always considered the typical lurid red form throw a preponderance of plants bearing rose pink flowers and approximating to those of the supposed "species" we know as *Rosa Fargesii*. It would seem, therefore, that RR. *Moyesii* and *Fargesii* are but colour forms of one species. Interesting information and worth knowing! *Rosa Moyesii*, however, is readily increased by cuttings or layers and had not it been raised from seeds in the first instance, we might have been long enough finding out the truth of the matter.

Very few amateurs will trouble to raise shrubs from seed even for the sake of finding out peculiarities such as the one mentioned, but there is no reason why every flower-loving amateur should not raise hardy perennials from seed. The gardener who has never raised anything more perennial than *Coreopsis grandiflora*—most gardeners raise that from seed—will do well to try his "prentice hand" on some comparatively easy and really interesting race of plants which will so whet his appetite

as to give him patience to await results with families even more interesting, but distressingly slow to germinate. Encrusted and Mossy Saxifrages are suitable, so are Aubrietias. All these produce a wonderful variety from seed and, given the proper compost, are free, easy, and fairly quick to raise from seed. The Aubrietias and Mossy Saxifrages are quickest. They should flower in just over twelve months from the date of sowing the seeds. The raising of Encrusted Saxifrages was explained in our issue of 9th inst., page 614. Any fairly porous open soil will suit Aubrietias or Mossy Saxifrages. The seeds may be sown at any time now in pans in a cold greenhouse or unheated frame. If given appreciable heat there is great risk that the young plants may "damp off." "Damping-off" is caused by a fungus (*Botrytis*), which seems particularly fatal to cruciferous plants. The Saxifrages should not be exposed to too strong sunlight.

Heaths are very interesting to raise from seed. There seems no reason to doubt that ericaceous

plants generally are unable to grow unless a special fungus is present in the soil. The matter has been investigated specially in connexion with the *Rhododendron*, but from the facts we may infer that this disability attaches to most members of the Heath family. In the case of mature plants no doubt the fungus is carried in their roots into new soil. They, consequently, do quite well in lime-free loam without peat or leaf mould, which are apparently fungus-carrying materials. It will be noticed, however, that self-sown seedlings never spring up in such soil. An abundance of good seed is produced each year and if a patch of soil a foot or so square be taken out adjacent to the Heaths and filled in either with well decayed leaf mould or peat, multitudes of seedlings will spring up in the prepared patch, though the surrounding loam never produces one.

The most interesting Heaths to raise from seed are *Erica cinerea*, any good and unusually coloured variety, *E. Tetralix*—again a variety is better than the typical form and the Irish Heath, *Daboecia polifolia*. The seeds should be mixed with a pinch of fine silver sand and be sown in pans of almost pure peat or alternatively a mixture of light but mellowed loam and leaf mould in equal proportions. The pans should be watered before sowing and no attempt need be made to cover the seeds, which should be kept dark and fairly close until germination takes place, which will be within a few weeks. All the plants will be interesting and it is quite on the cards that something really good and worth sending out may turn up. The Irish Heath is a very variable plant and by cross-pollinating

A GOOD FORM OF VERONICA SPICATA.

Daboecia polifolia (purple), with the globose white form, usually listed as *D. p. globosa albo*, a great variety of globose forms may be obtained of rosy-lilac and silvery-lavender shades of colouring.

Other shrubs really worth raising from seed are the Brooms. The white Portugal Broom, *Cytisus albus*, comes readily from seed, indeed, it self-sows itself freely in the border. The Common Broom (*C. scoparius*), naturally, reproduces itself freely from seed, so does the very distinct form called the Moonlight Broom (*C. s. sulphureus*). The crimson and gold variety *Andreanus* throws about 25 per cent. of plants approximately true to type and a further considerable percentage of which the flowers show more or less crimson staining on the golden blossoms. The hybrid Brooms, such as *præcox*, *kewensis*, *Beani* and *Dallimorei* are interesting when raised from seed. Most of the seedlings revert more or less to one or other parent. These Brooms may be sown in drills outdoors, but they are rather tap-rooted so that if only a few are wanted it is as well to sow them in pots so that they may be transplanted into their permanent quarters with the least possible disturbance.

Of herbaceous perennials, Gaillardias are readily raised from seed and have a better constitution when so obtained. The soft yellow self forms, such as *Lady Rolleston* and *E. T. Anderton*, are rarely obtained, however, and the seedling plants in general are more useful than interesting. The Goat's Rues—forms of *Galega officinalis*—come fairly true from seed, though such as *Her Majesty* and *Hartlandii* are apt to lose in size of blossom and truss. The form called *G. o. rosea fl. pl.* comes quite true from seed and, strangely enough, self-sows itself freely. Geum species come true from seed, but the fine form of *Geum coccineum* called *Mrs. Bradshaw*, which is almost certainly identical with the older *Winchmore Hill* variety, rapidly deteriorates from seed, so that many stocks of this plant now in existence, are little, if any, better than an ordinary form of *Geum coccineum*.

German Irises are only worth attention from seed if one is prepared to follow up one's results and engage in plant breeding systematically. A very small percentage of the seedlings attains the standard of the selected parents, let alone surpasses it.

The Veronica family is not a particularly suitable one to raise from seed, but it is interesting to raise a batch of *V. spicata*, for instance, if only to note the immense diversity in habit, spike and foliage among the seedlings. Some of the plants will be quite white and woolly, others entirely glabrous.

Carnations and Border Pinks are interesting to raise from seed, though even the skilled plant breeder will, in the case of the former beautiful flower, hardly get one plant in three or four thousand which, after trial, appears worthy of a name! The Alpine Pinks present a better field to the amateur. Cross-fertilisation is here well worth attempting as some of the "mules" so obtained are both interesting and beautiful. *Spencer Bickham*, which we illustrate, may be taken as a case in point. This represents a cross between *Dianthus cæsius* and the Maiden Pink, *D. deltoides*. The grassy foliage is somewhat like that of *cæsius*, but smaller and closer, while the flowers obviously take after those of the Maiden Pink.

Anemone seeds are, generally speaking, slow to germinate, but many interesting forms have come to light in this way. The Japanese Anemone, for instance, has been greatly improved from seed of late years, but a batch of seedlings from a good variety always give interesting forms and, no doubt, further improvement is still in store.

Delphiniums everyone should obtain from seed. For grouping among shrubs, for soils not specially congenial, or for other situations where the plants may have to rough it somewhat, or, again, where stature is of the first importance, seedlings should be employed. There is no comparison between the vigour of a seedling and that of even the most robust of named varieties.

(To be continued.)

INTERESTING TO RAISE FROM SEED, *DABOECIA POLIFOLIA*.

WINTER FRUITING TREES AND SHRUBS

BY EDWIN BECKETT, V.M.H.

ONE is always pleased to read notes on trees and shrubs, such as those by "A. O." (THE GARDEN, December 9, page 615), especially if one happens to be an arboricultural enthusiast, but as I scanned these I felt that either too great a restraint had been exhibited, or that the writer had somehow or other failed to view some of the very best shrubs and trees that retain their fruits well on into the winter period, when flowers are not, and the bright seed pods thus become doubly useful in the shrubberies. In the hope of relaxing somewhat the otherwise rather hard and fast line set down (of course, I admit that this "line" may only be a child of my imagination), I have had a glance around to seek such additional wares as we can offer from Aldenham, and I do so in the hope that others of your readers will carry on the effort (if the Editor will kindly permit), and also relate their happy possessions, for I fancy the whole tale would indeed be interesting reading.

As a start I would dive into that large family of the *Cratægi* which is referred to. What an enormous group it is too, for there must be something like a thousand different "species and varieties" (American determination) in this country now (we actually have about 700 or 800 at Aldenham), and of these there are many still holding the bulk of their fruits, and appear likely to do so for some while yet! Those that have shed their burden did so as the result of one or two sharp snaps of frost, but many still hold, and of these I can well confirm the remarks ament *C. Carrierei*. We can go a little further with the record of the persistency of this, for we have actually had, on more than one occasion, the current season's fruit getting towards ripening while the previous season's still remained suspended from the same branches, no doubt, in fact, the result of mild winter seasons, though there may be other explanations. *Cratægus mollicula*, which is I believe unique in this country, among American Thorns, as having yellow fruits, still has these suspended and though a little shrivelled they look like hanging on for some time. Other excellent Thorns that as yet still carry most of their fruit are *C. Dammeri*, with plump, small elongated bright red ones; *C. opulens*, round, dull red; *C. Eganii*, small, round, rosy red; *C. cupulifera*, with many small, bright red; *C. Ellwangeriana*, with large pale red fruits, to which *C. Fulleriana* bears considerable resemblance and is also carrying well; *C. persimilis*, which is somewhat like *cupulifera*, but rather larger in size; *C. lanuginosa*, with medium sized bright red pomes; *C. Calvinii*, rather shrivelled, bronzy red in tone, carried in bunches, freely borne; *C. ferentaria*, having many small, deep red fruits, like large-sized Red Currants; *C. diffusa*, observable from a long distance with its wealth of bright red haws, while *C. beata* has similar effect, with lighter red fruits; *C. tucosa*, one of the earliest to shew, one of the most persistent, and certainly one of the brightest in colour, and so the tale might go on, though I have only mentioned a few of the best, noted at random.

The Fire Thorns have also been referred to, but surely two are missing in the forms of *Pyracantha Gibbsii* and *C. Rodgersiana*, that claim to be of the best, while *P. crenulata* also has its claims for inclusion. *P. Gibbsii* raised from seed sent home by Mr. E. H. Wilson, is to my mind one of the best of winter fruiting shrubs, and even at the present time can only be said to be colouring to perfection, so that one will readily see its great value, either as wall shrub or as specimen in the shrubbery,

with its many freely borne, closely jewelled bunches of bright red berries, that are most distinct from the *C. coccinea* group in size and colour and general appearance. *C. Rodgersiana* is a yellow fruited species, unique therefore and decidedly worth its place at this season, when it is just assuming its deepest tones. It seems almost a pity that, later on, the birds will claim tribute from these!

Almost mechanically one proceeds to the *Hippophæes* which makes one rather wonder at the previous omission of the kindred and type plants

growths of small crimson berries, that are decidedly in keeping with the shrub's pretty habit and long arching delicate growths; *C. Simonsii*, resplendent with many large-size bright crimson berries; *C. amona*, freely fruiting, and *C. rupestris*, which besides carrying many cheerful-looking red berries, also bears as many crimson-toned leaves among its dark green foliage, while the claims of such varieties as *C. divaricata*, *C. horizontalis* and the pretty ruby-red fruited *C. buxifolia* of tiny foliage, are little more urgent, if at all, than a score of others.

FRUITS AND FLOWERS OF THE STRAWBERRY TREE, *ARBUTUS UNEDO*.

of the *Rhamnaceæ*, viz.—the true Buckthorns (*Rhamnus*), which at this season of the year are so conspicuous with their many bunches of shiny black, freely borne fruits (black for the majority of the species, though some of the others are rather of a purple tinge), and of these *R. cathartica*, *R. Erythroxyton*, and *R. utilis* are assuredly among the most striking fruters we have at present, and the birds certainly respect them here. Another quaint black-seeded bush is *Zanthoxylum piperitum* which we have well covered at the moment.

Cotoneasters are almost multitude, and many of them are carrying their fruits besides *C. rotundifolia* and *C. frigidula*. Good as the last named is, it is absolutely outclassed by its own variety, *C. frigidula Vicarii*, not only as regards size of foliage, but essentially so when comparison of it is made as against the larger fruits, carried more freely in bigger bunches, of the variety, in fact this is probably the gem of the whole garden at this period and can be identified at a long distance owing to its bright crimson aspect. Others that are beautiful are *C. salicifolia rugosa*, with its crimson berries and the delightful red-bronze appearance of its leaves, which might almost be taken to have been carved out of metal, so beautiful is their sheen; the allied variety, *C. salicifolia floccosa*, so freely carrying its long raceme-like

Berberises, of which only two are mentioned, also must enter the field here, and one must of necessity restrict again to the very best, though, with such an enormous genus as this one, a score could again be dealt with. The first to which I would refer are two black-fruited evergreen forms from China, both with most interesting looking foliage, viz. *B. Gagnepainii*, with long medium-sized fruits that peep out around the leaves, and *B. Juliana*, less in size, and even more shy; both of these are rendered more conspicuous and interesting by the grey-purple bloom that covers the fruits. Claiming more attention with their bunches of red fruits are *B. Wilsonæ* and *B. Girardii*, the latter also being remarkable just now, through the red tones of its leaves, while finally I would refer to *B. orthobotrys*, with its large deep red fruits of elongated shape, and *B. brevipaniculata*, which, resembling in appearance the previous species, has large translucent red fruits at this season.

The claims of *Symphoricarpos racemosus* are admitted, but here again a variety (or perhaps I should write a presumed variety, as it is a little doubtful of origin), quite dwarfs the typical form. The variety referred to is known as *S. racemosus laxigatus*, the fruits of which are larger and of more regular size and born in racemes, which often attain, in a well grown plant, from 2ft. to 3ft. in length. The fruits of this also appear to hang

for a much longer period and are certainly, so far as I can ascertain, left severely alone by our feathered friends.

There are several other plants of great beauty in fruit and reference to the Siberian Crab calls to mind the yellow fruited form *Pyrus baccata fructu-flavo*, the fruits of which have certainly turned for the most part a pretty cinnamon brown in colour, though some maintain their very bright yellow shade, and only a very few have so far dropped off. Two other Crabs must have mention. *Pyrus Malus aldenhamensis* still bears the majority of its reddish-purple "cherries," and *Pyrus Scheideckeri* carries most of its small yellow fruits.

Among Roses, the Chinese *R. Helene* now "queens" it with a wealth of small copper-red berries, borne freely in many bunches, and where the large "apples" of the Ramanas Rose (*R. rugosa*), from the neighbouring Isles of Japan, is early-on the victim of the birds, the latter, to the great gain of the garden, do not seem to trouble about the Chinese beauty. *R. lucida* and *R. nitida* are two other species that are particularly pretty low-growing genus at present, with much fruit.

Three *Viburnums* look fine now; *V. Opulus*, carrying a quantity of deep red drupes; its yellow fruiting variety, *V. O. fructu-luteo*, even more striking; and *V. Sargentii*, similar, yet dissimilar to the first named, bearing its many darker red fruits in good contrast thereto.

Ruscus aculeatus (the Butcher's Broom) is bearing fairly freely its bright red berries set deep in its evergreen foliage, and there is a very fine improved form of this (introduced, I fancy, by Mr. E. A. Bowles), which puts the original into the shade for size of fruit and freedom of fruiting. *Lonicera syringantha* looks charming now that it has shed its foliage, on account of its many twin drupes of orange-yellow, and in good contrast to this there are the bunchy black fruits of *L. Henryi* and the red ones of *L. Maackii*. *Stranvasia Davidiana*, and the lower-growing species, *S. undulata*, are also freely fruiting now and look charming with their pure crimson berries and evergreen foliage.

So might the tale run on, for there seem countless plants to which reference could be made, but one must pity the patience of Editor and printer, and beyond reference to the names and colours of *Hypericum Androsarum* and *irabum* (both black), *Arbutus Unedo* (with strawberry-like red fruits), *Taxus baccata* (drupes of both translucent red and yellow), one must be brief to leave final note of two specialities from China, both sent home by Wilson. *Pyrus Malus transitoria tormigoides* (with foliage like a Hawthorn), is a wonderful sight at the present time, even though many fruits are down, for two trees that we have here are still literally smothered with the bright red-tinted fruits, like white-heart cherries in appearance, while *Cydonia japonica Wilsoni*, despite heavy winds, still manages to retain many of its extraordinary fruits, that look like very large-sized green lemons, closely hugging the branches and it is rather a curious sight to see a comparatively small tree carrying an enormous crop of these, for I have counted well over fifty on a slender tree only about 12ft. to 15ft. high.

This year has been a truly wonderful one for fruiting trees and shrubs. Probably owing to the ripening effect of last year's long, hot summer, such fruits as rose hips, etc., have been borne with great freedom. One of the finest sights at the present time is presented by the Hollies, both red and yellow fruited; probably few of us will ever see them in greater perfection, for, looking back on the years, they appeal to me as being far better than I have ever seen them in the past.

THE CHRISTMAS ROSE

THE Christmas Rose would scarcely be held in high esteem if it blossomed at a season when flowers were plentiful; for the rather saucer-shaped blossoms, though substantial, are not, as a rule, a very pure white, being tinged with the chlorophyll which colours the true leaves and stems. The flowers come very much purer in colour if grown under glass or even given the protection of a hand-light. If they are to be cultivated primarily for cut flower, it is wise to grow them where such protection can be afforded without difficulty and without creating an eyesore. Hand-lights or bell-glasses, however, detract immensely from the beauty of the plants as growing, and half the charm of the Christmas Rose in the garden is to see its clustered blossoms braving inclement weather outdoors. The Christmas Rose likes a moderately rich not over-light soil in semi-shade. The flowers are tough and not easily destroyed by frost. It is wise, none the less, to give the plants a westerly exposure rather than a site

until two whole years have elapsed. If, however, home-saved seeds are sown as soon as ripe (about May or June) germination will take place early the following spring. With good culture plants blossom in three to four years from seed. Seedlings are much more vigorous than plants which have been increased for several generations by division. With seeds such as these, which require some time to germinate, it is usually better to sow in square seed-pans and stand in a cold frame rather than to sow outdoors. It is easier to keep pans quite free from weeds than it is the open-air seed-bed, also the young plants are more easily divided when it becomes necessary to transplant.

The typical form of *Helleborus niger* is hardy and useful for outdoor culture, but there are several selected forms with larger or whiter blossoms. Probably the best of these is called *maximus* or, sometimes, *altifolius*. It is an early bloomer, being usually at its best in November. The flowers are often tinged with rose. *H. n. carnea*, sometimes called Apple Blossom,

THE CHRISTMAS ROSE, HELLEBORUS NIGER.

where the morning sun can penetrate to probably frosted blossoms. A ferny bank, the western edge of a wood, spinney or matured shrubbery, the partly overgrown bank of a pool, sheltered corners in the bamboo dell—all are suitable places for this lowly but always welcome flower. There are few gardens which have not places ready-made for them, nor, if all suitable sites are otherwise occupied, is it difficult to arrange a little corner for their accommodation. On light soils cow-manure should be incorporated in the soil before planting. As the clumps should remain many years undisturbed, it is well to trench the ground deeply before planting takes place.

Early autumn is the best time to transplant the crowns. Propagation is by division or seeds. Named varieties must, of course, be increased by division. Few amateurs, however, have the heart to divide up a fine, well established clump, so that the hardy plant nurseries always do a good trade in these plants. Seeds, if sown in January, will not, under the most favourable conditions, germinate before the spring of the following year, and the seedlings may not appear

has almost black stems and dark foliage, and the blossoms are flesh-tinted. Of the forms noteworthy for purity of colouring mention may be made of *St. Brigid* and *Riverstoni*. The form called *major* is desirable, and very robust and free-growing.

Like most tuberous-rooted perennials—*Paeonies*, for example—the Christmas Rose is impatient of transplantation. Patience is therefore very necessary when establishing a new colony, since really imposing results cannot be expected for, at any rate, two or three seasons.

There are in some gardens large patches of these plants which can hardly be said to look natural as growing, simply because the plants are planted quincunx fashion with mathematical accuracy, at a distance apart of from 2½ft. to 3ft. Now the Christmas Rose must have room if it is to grow into imposing clumps, but 2½ft. is an "outside" distance to allow between the clumps and it is quite easy to arrange the plants in drifts and little colonies without such regularity of spacing. An evergreen backing is very desirable.

WOOD LILIES

A SMALL group of woodland plants, chiefly natives of North America, the genus *Trillium* contains about thirty species, of which the best known and favourite kind is *T. grandiflorum*. Other two or three species are found in North-Eastern Asia and Japan. In habit they bear a great resemblance to each other, with the characteristic three leaves in a whorl, borne on a stem varying from a few inches to a foot or more in height. Arising from these three leaves is the flower, also with its parts in threes, borne either on slender stalks or, quite sessile, at the junction of the leaf petioles.

The *Trilliums* are quite hardy, and easy to grow in cool, shady spots planted in a mixture of loam, peat, leaf-soil and sand. As they flower early, a sheltered place protected from cold winds in spring is essential if they are to be seen at their best. *T. grandiflorum* may be naturalised in the open woodland, provided the soil is rich and moist. Most of the other kinds are desirable plants for the rock garden or bog garden, in the former of which many cool sites may be selected for their reception. While not absolutely essential if the soil is moist, shade is desirable for all *Trilliums*. The best kinds and their peculiarities are given below.

T. GRANDIFLORUM is a well known plant, familiar to most garden-lovers. When planted in a suitable spot it increases freely, throwing up clusters of pale green leaves that are bronze tinted when young. Each stem bears a solitary, nodding, white flower, measuring some 4ins. across. The flowers become tinged with pink after a time, but are none the less charming on that account. For woodland walks, where the soil is rich with humus and where there is plenty of moisture, this is an ideal plant for massing. In such positions it will reach a height of 2ft. or more, each stem carrying its large nodding flowers in early May. There are numerous forms of this species, some with small, others with large flowers. Most distinct of all is the variety *roseum*, a charming variation from the type with flowers which open

a pale blush pink, deepening in tint to rose before they fade.

T. sessile is a robust-growing kind with broad, ovate leaves in threes, coloured sage green, with

spotted as in the type, but bears variable white flowers in April that are claret tinted only in their lower parts. Like the type, it is fragrant, but it is more vigorous in habit, often attaining to a height of from 2ft. to 3ft. in favoured situations. *T. sessile* and its varieties flourish in boggy soil.

THE RATHER UNCOMMON TRILLIUM SESSILE CALIFORNICUM.

numerous paler green and purple spots. The flowers are sessile in the axils of the leaves, and consist of three chocolate-coloured, strap-like segments 2ins. or 3ins. long. Although not an attractive plant, the flowers are deliciously fragrant. A much more desirable plant is *T. sessile* var. *album* (syn. *californicum*), which has leaves

T. ERYTHROCARPUM is a charming little plant for a selected nook in the rock garden. It has spotted ovate leaves and showy white flowers that are heavily spotted with crimson. It is more difficult to establish than most of the others, preferring a drier position in well drained soil.

Of the other kinds in cultivation there is *T. CLERMUM*, with pretty, nodding, white flowers that are fragrant and measure 1in. across. *T. ERICETUM* has dark green foliage and reddish purple flowers in the type. There is, however, a white-flowered variety that is suggestive of *T. grandiflorum* when doing well, often reaching a height of 18ins. The petals, however, are tinted with a livid red colour at the throat or base. *T. OVATUM* is a dwarf plant whose three leaves form a complete circle round the stem. The almost sessile flower is pure white at first, but develops a red tint with age. It should be grown in a sheltered position in the rock garden. *T. NIVALE* may be called a miniature *grandiflorum*, bearing its pure white flowers in April. It only grows to a height of 3ins. or 4ins., and does well in drier peaty soil. Another dwarf rock garden species is *T. RIVALE*, which must not be confused with the above. It has white flowers, produced in March, more or less covered with purple spots in the lower half. It is a charming little plant and also easily grown.

T. RECURVATUM is more curious than attractive, with flowers the segments of which are ruddy purple in colour and much recurved. A variable plant is *T. STYLOSUM*, which is easy to grow where *T. grandiflorum* flourishes. The flowers are not so large as in that species, and are usually rosy pink in colour, but the colour varies considerably. When well grown, plants reach a height of 2ft. It is one of the later flowering kinds, often not

BEST KNOWN OF WOOD LILIES, TRILLIUM GRANDIFLORUM.

opening its flowers till June. Tillands are best left undisturbed when established, when many of the species will soon make respectable clumps. For the purpose of propagation they

may be lifted in autumn and the roots be divided. They should not be allowed to get dry; indeed, they should be planted again at once. W. L.

RARE ALPINES AT HINDHEAD

NEAR to Haslemere, where my late good friend, Professor Sir Isaac Bayley Balfour, came to pass his last days, the doctor of the place grows alpinists with the greatest success. We met at Chelsea Show and he took me in his motor through the beautiful Surrey countryside—nice villages, hills covered with picturesque Scots Pines and Gorse. At Hindhead the little cottage garden is kissed by the evening sun and its beauties are now at their best. Imagine a paved path adorned with the rarest of alpinists, growing there like weeds:

Linnaea alpina in masses everywhere, *Viola losniaca* and *V. calcarata*, *Saxifraga cæsia*, *SS. bryoides*, *aretioides*, *Grisebachii*, *Gentiana verna* (which I would rather call *floribunda*), *Thlaspi rotundifolia*, *Draba pyrenaica* and *D. p. alba*, *Pentstemon rupicola*, *Origanum Dictamnus*, *Campanula Allionii* and *C. A. alba*, *Dianthus Freynii* and *D. microlepis*, *Lithospermum* of all kinds, etc., all growing freely in full sun at Hindhead.

This would please Professor Tyndall, who declared that that part of England has the purest air and is the best place in which to take a change

in the kingdom. In picturesque rockeries were the *Gentians* of the Alps (*Lavaria*, *verna*, *brachyphylla*), and those of Asia (*Farreri*, *sino-ornata*, *Pardoni*, etc.), *Ranunculus pyrenaicus* in full flower, *Primula marginata* and *PP. viscosa*, *deorum* and *fariosa alba*, *Saxifraga aizoides* and *SS. baldensis* and *vallensis*, which Dr. Jenkin found near the Mont Cenis hospice, where it had not previously been discovered, *Anemone sulphurea* in flower, and *A. vernalis* also, with seventeen beautiful flowers, *Meconopsis* in variety, even the rare *Prattii*, *Aquilegia glandulosa* and some nice *Sempervivums* such as I had not seen at Kew the previous day. All these gems looked well and as healthy as they are on the highest summits.

Then, in a frame kept well up for the sake of a good drainage, in nice little beds facing the evening sun, were *Azalea procumbens*, flowering as well as at the highest altitudes, near to 6,000ft., *Androsace glacialis* perfectly well, *A. Vitaliana*, *Phyteuma hemisphaerica*, *Saxifraga retusa*, *S. aspera*, grown from seeds, *Campanula cæsia* and *C. c. alba*, *Ranunculus glacialis*, *Daphne arbuscula* and *D. tangutica*, some rare *Primulas*, *Lobelia linnæoides*, *Gentiana chionantha* (*verna alba*), etc. In a collection of pots, nursed as if they were little children, were *Phyteuma comosum*, *Campanula excisa* and *C. Zoysii*, *Androsace imbricata* (from seeds), *pyrenaica* (*idem*) and *Gentiana bavarica* in a pot filled in the middle with sphagnum moss or peat, in order to provide a regular supply of water to the plant.

In such a botanic garden, time passes and night falls too early. I often dream of the little garden of my friend the Hindhead doctor and my hope is to see it once again.

Floraire, Geneva.

H. CORREVOY.

CAMPANULA CÆSIA IN DR. JENKIN'S ROCK GARDEN.

A FINE PLANT OF SAXIFRAGA ASPERA IN THE SAME GARDEN.

AN ALPINE "BLUE DAISY"

THERE are several so-called "Blue Daisies" for the rock garden, none of which is either a Daisy or blue. *Erigeron leionerus* is the best and prettiest of them all, a delightful, thrifty little plant, forming compact carpets of narrowish leathery leaves half an inch high and carrying in May or June a generous crop of lavender blue Daisy flowers on stiff, erect stems only 2ins. high. It is like a tiny, very dainty edition of *Aster alpinus*.

I shall never forget my delight when I first discovered this plant. It was growing amid wild rocky scenery, perched high and dry on a little promontory of gritty soil above a rushing mountain torrent in what is, without a doubt, the richest hunting ground for alpine plants in all the world. I have made expeditions of many thousands of miles in search of rock plants, I have been to Mt. Cenis, the Lantaret and Mt. Baldo in their fullest flush of flower-time, but I can say quite truthfully that for brilliance and profusion of flower, as well as for endless variety of priceless rarities and special forms, no other place I have ever visited comes anywhere near that little strip of rocky country where I first discovered *Erigeron leionerus*. It is more marvellous in richness and variety and in rarities, and has a stranger geological formation than anything that even Farrer has described in "On the Eaves of the World." Yet the flower-time is strangely short. You must time your visit to within a day or two, or you will find little or nothing of interest.

If you will promise not to divulge the secret to a soul, I will tell you where this richest of all collecting grounds is—among the rock gardens

at Chelsea Show. So now you can go and collect there to your heart's content, taking what you will and as much as you will, and the more the better, with no qualms of conscience about being

which flower profusely. Any decent lawn suits it. It is happy, too, and appropriate in the moraine, and is an ideal plant to put in the alpine flower lawn of mixed dwarfs without grass. This

equally graceful appearance, and the dainty prim little Pompons, was remarkable. But there was no abrupt transition, for between them were many vases of highly decorative singles and Dahl. Baldoek, a deeply coloured form of Baldoek's Crimson, which is grown so extensively for market purposes. Dr. Jacobs is a valuable decorative variety of crimson colouring, as also is the golden chestnut Teresa. Messrs. Scott and Wickham had a nice batch of the new Golden Butterfly, which we illustrated a fortnight ago, while Mr. Norman Davis again staged Pink Favourite, shewing, in both instances, that they are good winter-blooming varieties. Mr. Isaac Godber had several vases of Golden Star.

In many ways the best floral exhibit was that of the magnificent plants of Begonia Gloire de Lorraine sent up by Mr. J. B. Body. Each of the many very large plants was a splendid example of the highest cultural skill, and the myriads of bright pink flowers made a welcome feast of colour. There were also bright colours in the several Carnation exhibits. Messrs. Allwood Bros., had their usual good collection. In Eileen Low and Mrs. T. Ives Messrs. Stuart Low and Co. had two good pink sorts, while Lord Lambourne and Red Ensign provided brilliant colouring. Yvonne Holmes, a pinkish Perpetual Malmaison, Boadicea and Laddie were well set up by Mr. C. Engelmann.

A very uncommon exhibit at this season was the collection of pot plants of the beautiful blue Morning Glory, Ipomoea rubro-cerulea, by Messrs. Sutton and Sons. These were all excellent plants and although, owing to the cold, the flowers were tightly closed during most of the afternoon, the late comer could readily imagine what a glorious display they would make in a warm greenhouse.

Quite a spring-like effect was made by Mr. G. W. Miller with his long collection of Polyanthuses and Double Daisies, in neat, shallow baskets. This was a direct contrast to the conifer collection of Mr. G. Reuthe, though the great variety and the small collection of cones were of interest.

Some useful alpinists and his quaint miniature rock gardens were displayed by Mr. F. G. Wood, who also shewed his "Optical Square or Cross Sight," a handy little pocket instrument of great value for easily setting off straight lines and right angles when garden making.

Winter-flowering Sweet Peas were again arranged by the Rolvenden Nursery Company; the bloom-

THE PRETTY "BLUE DAISY," ERIGERON LEIOMERUS, IN THE MORAINE.

a vandal and stripping the Alps. I captured a dozen good roots of Erigeron leiomerus there in 1912 (in English it is called Fleabane, but what can we think of a flea to which such a flower is distasteful), and on my usual principle planted it out on my rock garden to find out if it were a grower or a dier, and if it were perfectly hardy. If a plant is not perfectly hardy and growable, then let it get on with it—and die, say I; but there were no buts about Erigeron leiomerus. It grows sedately but steadily, forming neat mats,

last form of alpine gardening is a recent discovery of mine, and is going to become as important as the moraine. After a year or two in one place E. leiomerus is apt to grow leggy—in its small way—but an occasional top-dressing soon remedies this, or the plant may be dug up, pulled to pieces and transplanted. This is the best and easiest way of increasing it. If you wish to go further afield to collect it, I believe E. leiomerus is a native of North-West America.

Svenenize.

CLARENCE ELLIOTT.

THE LAST SHOW OF THE YEAR

ALTHOUGH it was not large, the last R.H.S. Show of the year at Vincent Square on December 12 was very bright and interesting. Orchids were of especial merit and from the novelty point of view the most important. In addition to the six which we describe, another received recognition. This was Cypripedium Etta, shown by Mr. R. Windsor Rickards, but its place could not be found. The wire cage for the new Orchids seems to have been quite overlooked of late; but, judging from a recent correspondence in our columns, a similar arrangement for special fruits would be an advantage for all legitimately concerned.

The outstanding Orchid exhibit was the gold medal collection of Cypripediums by Mr. G. E. Moore of Chardwar, Bourton-on-the-Water, and this was noteworthy for the great cultural skill it illustrated, as well as for the value of the many varieties on view. Mr. H. L. Pitt also had a valuable collection of Orchids. His Cypripediums were prominent, but the outstanding plant was a superb specimen of the brilliant Labio-Cattleya Majestic. Messrs. Sander and Co. also had a good group in the body of the hall.

Chrysanthemums were displayed well by several growers. Messrs. Keith Luxford and Co. had a pleasantly arranged collection of nearly all the different types, each of distinct decorative value. The contrast in size between the immense, yet

graceful exhibition varieties such as Ida, made up of elegant, narrow yellow petals flushed with rose with age, and Helena Margerison of

CRIMSON BERRIES AND GLOSSY FOLIAGE OF STRANVÆSIA UNDULATA.

were better coloured than a fortnight ago. Flamingo and Mrs. Kerr, two pink flushed varieties, were bright and daintily charming, while Princess was very chaste and beautiful. The blooms were well disposed on sufficiently long stalks for dinner table decoration and for small vases. The stems are not so stout as the summer-flowering varieties, so the blossoms are easy to arrange

NEW AND RARE PLANTS.

Chrysanthemum Cuerton Sunflower. This single variety is remarkable for two things, its beautiful colouring—it is a soft and yet bright yellow—and its freedom to flower. The flowers are shapely and, we are told, very lasting, but withal on the soft side. It would be useless for market or for sending by post, but for conservatory decoration or for cut flower it should have a future. Though larger in blossom, it is of the Mary Anderson type. Shewn by Mr. S. Aish.

Primula sinensis fl. pl. var. Rossway Beauty.—A cultural commendation was given for two very fine pots of double Primula from Major-General Sir Charles F. Hadden, K.C.B., Berkhamsted. These plants were evidently of a robust strain as well as admirably grown. The flowers were tinged with cattleya-mauve, pointing probably to a stiff soil with a distinct iron content. These double Primulas are especially valuable for florists' work.

Stranvæsia undulata.—The chief beauty of this spreading Chinese shrub lies in its abundant brilliant red berries, which are produced in clusters and, individually, have somewhat the appearance of unusually showy Hawthorn fruits. It is an evergreen, and the dark green shining lanceolate leaves, which are 2 ins. to 3 ins. long are an added attraction. This hardy shrub bears plenty of small white flowers in early summer, but the petals

soon drop. It was introduced by Wilson at the beginning of the century when he was travelling for Messrs. J. Veitch and Sons. Award of merit to Mr. Lionel de Rothschild.

Cypripedium Golden Fleece.—This is one of the best of the yellow Lady's Slipper Orchids. The plant had a pair of large graceful blooms standing erect on long stems. The pouch and lateral segments are of shining golden yellow colour while the standard is mostly creamy white with a few spots at the base. Award of merit to Sir George Holford.

Cypripedium J. M. Black.—This is a magnificent Lady's Slipper Orchid which might almost be termed a glorified and beautiful Cypripedium insigne. It was a robust, green-leaved plant and the large flower was carried well. The large upper segment is nearly all white, though the base is flushed and has a few rosy chocolate spots. Award of merit to Messrs. Flory and Black.

Odontioda Royal Scot.—The plant bore a long erect spike well furnished with perfectly shaded flowers of more than average size and of bright chocolate colour well margined with white. Award of merit to Messrs. A. and J. McBean.

Odontoglossum Vega.—This is another beautiful Orchid bearing perfectly formed blooms. The colour is a rich, intense maroon and the segments were very finely edged with white, making it a very uncommon flower. First class certificate to Messrs. A. and J. McBean.

Sophro-Lælio-Cattleya Lustre.—The most gorgeous of all the new Orchids. The flowers were of medium size, but of dazzling cerise crimson colour. Award of merit to Messrs. Charlesworth and Co.

Vuystekeara Aspasia.—This is an interesting and beautiful example of the orchidists' hybridising art.

First, some time ago, *Odontoglossum* and *Cochlidia* were crossed, giving rise to the new genus *Odontioda*. Later, and much more recently, *Odontioda* and *Miltonia* were successfully crossed and this new genus received a very ugly name, though all its members have beautiful flowers. The latest is *V. Aspasia*, which shows a deal of the *Miltonia* parentage in the large flattish lip, which is flushed and spotted with mauve. The other segments are of rich velvety crimson colour, faintly edged with a paler shade. The combination of colouring makes a singularly beautiful flower. First class certificate to Messrs. Charlesworth and Co.

SOME MUSK ROSES

THAT delightful Himalayan Briar *Rosa Brunonii* should be in every collection of Rose species. It is a prodigious grower and profuse bloomer when established. There seems to be some confusion with these Rose species. I always look upon the variety known as *R. polyantha grandiflora* as a near relative to *Brunonii*. In any case, both are worth growing. As with all the Musk Roses, huge panicles of bloom are a feature of *R. Brunonii*, and the pure white flowers with profusion of yellow stamens have a simple beauty all their own. Closely allied to this is one *Mme. d'Arblay*, a semi-double white, and also a rampant grower. The wood is apt to suffer in a hard winter. A grand variety of the Hybrid Musks that every lover of single Roses should possess is *Miss Florence Mitten*. I know of no Rose that so persistently holds its blossoms, and the large Apple blossom pink flowers remind one of a glorified *Alexandra Day* Rose. Unlike the others I have named, it is a more compact grower and blooms right down to the ground. J.

A SEVEN-INCH POTFUL OF THE DOUBLE PRIMULA, *P. SINENSIS* ROSSWAY BEAUTY.

SOFT GOLD SINGLE CHRYSANTHEMUM CUERTON SUNFLOWER, OF "MARY ANDERSON" TYPE.

CORRESPONDENCE

GRAFTING CLEMATISES.

I WAS pleased to see a criticism by so great an authority as Mr. Jackman of the article on page 567, on "Own Root Clematises." I read the article through carefully and, like him, I should have expected to have found the familiar initials "W. R." at the end. When I did not, the words of the blind Patriarch in Gen. xxvii, 22, came to my mind. One fails altogether to understand how the mind of so great and respected a gardener as "W. R." should have become so obsessed with this fallacy about grafting one Clematis on the roots of another, or why for years he should have written so persistently against

it to the perplexion and discouragement of many amateurs. He always seemed violently opposed to those who did not agree with his own views, and for long years any reference to grafted Clematises or the root-pruning of fruit trees would bring a sharp reply from Gravetye. In the fourth paragraph of his article "E. M." states a fact which, in the interests of his contention, he might well have left unwritten. When it was seen that the scion had itself formed roots why was it necessary to cut away the stock? No intending planter should be discouraged by this mischievous theory, but when the grafted plant comes to hand, plant it with the point of union deep enough for the scion to grow away on its own roots. If by any accident the stein should be cut to the ground, it will push up new growth from the eyes under the surface. Such an accident happened here to a plant of Nellie Moser on the south side of a fence, and a photograph of this plant which was taken two or three years later is reproduced on the cover of THE GARDEN of July 15, 1922. The same thing

FRUITS AND AUTUMNAL FLOWERS OF THE JAPANESE QUINCE.

happened to another plant here last spring which had been recently planted, but I did not despair about it, and, true to expectation, it simply threw up a stronger growth and probably did better through being cut down. There is a mystery about the sudden collapse of plants which can hardly be traced to grafting, or one would expect the trouble to be common to all gardens where grafted Clematises are grown; but this is not so. There is not a large number of Clematises grown in these gardens, but still, we have them in every aspect—on walls, fences, arches and bushes, north, south, east and west—yet I have never known or heard of the loss of a plant from this cause. Friends at East Grinstead, four and a half miles distant, could tell a different tale. Why? We make no special preparation—they go to much trouble and labour, and yet the plants will die. I have

struck cuttings, or slips, in late spring, and I have grafted plants, and both thrive. Thirty years ago I was a propagator in a nursery, and I often amuse myself doing such things if only to keep my hand in. If the trouble is ever traced, it will probably be found due to local conditions in the soil or otherwise.—H. C. W., *Lingfield*.

ROSES FROM HOLLAND.

IT may interest others to know the following facts. For the first time in my twenty-five years' experience of gardening I was tempted to send an order for a few Rose trees to one of the largest Dutch growers. The following are the particulars of the transaction: October 12, posted

during transit they would have been worthless. They are grafted on English Briar stock, and are about 75 per cent. cheaper than the list prices of English growers. Notwithstanding all this, never again will I touch them.—A LOVER OF ROSES, *Birkenhead*.

EARLY SNOWDROPS.

YEAR after year there have been letters in THE GARDEN reporting the early flowering of Snowdrops, but it generally seemed to me that they were not early. Therefore I report that this year they were in flower in this garden on December 8—THACKERY TURNER, *Godalming*.

ABOUT NERINES.

I READ with much interest Mr. Jacob's article on above. N. Bowdeni does splendidly with me here out of doors and always flowers profusely, but this year it was quite three weeks later than usual, and in consequence all the blooms were spoilt by frost early in November. I have not found that the hybrids of Bowdeni flower as well out of doors: possibly they may do so in Cornwall. Mr. Veitch has his Bowdeni hybrids, I think, in a very sheltered position at Exeter.—H. G. HAWKER, *Ermington, Devon*.

FLOWERS AND RIPE FRUITS.

I AM sending you a print shewing fully developed fruits and newly expanded flowers on a spray of the Japanese Quince, *Cydonia japonica*, which I think may be of interest, though such is by no means an uncommon occurrence. The contrast between the brilliant, almost scarlet flowers and the greenish fruits is very striking. Oranges and Lemons, of course, produce flowers and fruits simultaneously and even among shrubs hardy in this country we have the Strawberry Tree, *Arbutus Unedo*, the fruits of which take a year to develop and ripen. This late flowering of the *Cydonia* is, however, really more on a par with the second cropping, which is so common with Pears and Plums (especially Victoria Plum), and, occasionally, with Apples. The tendency towards such second cropping can be developed by careful breeding, as witness autumn-fruiting Strawberries and "perpetual" Raspberries.—H. H.

SPIDERY CHRYSANTHEMUMS.

AS I acted for many years as editor of the National Chrysanthemum Society's Official Catalogue, a publication which it is to be regretted no longer appears as of yore, I had some part in the classification of exhibition Chrysanthemums. I quite remember the term "spidery" being first applied to a certain well marked and distinct kind of Chrysanthemum which first appeared over thirty years ago. It is therefore a little difficult for me to understand what your contributor means on page 601 when he says "varieties of the spidery-petalled section (e.g., Rayonnante).". The variety "Rayonnant" (sic) and its near relatives do not, and never did, belong to the spidery group. All these thin, tubular, stiff-petalled forms, a small group, and at one time but little appreciated, were commonly known as the Hedgehog type, but no official section was created. The Spidery group, subsequently thrown together with a number of nondescript oddments, consisted of those peculiar Japanese forms with long, thin petals curling and twisting in a weird, fantastic form that placed them outside all recognised exhibition sections. The term "spidery" is a distortion of the late Shirley Hibberd's invention "spiderkry." He applied it to a form which he illustrated in the *Gardeners' Magazine* many years ago when I assisted him in the preparation of a Special Double Number devoted entirely to the Chrysanthemum. The original flower was grown in the gardens of the

order with remittance. October 10, acknowledgment received. November 16, made enquiries by letter re the dispatch. November 20, received reply that they had been sent on November 11, but giving no particulars as to route or anything else. November 23, wrote again, asking for these details. November 29, received reply to say half had been sent on November 15 and half on November 18 *via* Hull. There are half a dozen railways in this district that have connexions with Hull, so I had to enquire of each for tidings of this parcel—without result. I wrote to a friend in Hull who, after some trouble, traced the lot, and they arrived here in *one bundle*, not two, late on December 6. In the meantime I had lost the pick of the weather for planting. Furthermore, they were just packed in a bundle of straw, with the roots fully exposed; had there been frost

Emperor of Japan, and a photograph of it was reproduced by Mr. Hibberd with the odd name he invented being applied to it. "Spider" suggested the form and "kry" was a playful abbreviation of *Chrysanthemum*—C. HARMAN PAYNE.

THE TRIUMPH.

The Sun looked down on the garden
From the height of his summer power
And smiled to see Earth's happiness
Told forth by many a flower.

He breathed the Lilac's incense
Borne on the quivering air,
Saw the vestal Lily with downcast eye,
And the Iris of form so fair.

Yet some there were which slumbered,
From whom no answer broke;
The Hellebore and the Snowdrop,
The Cyclamen under the Oak.

His message in their sleep these heard:
"While I ride on high—rest on;
But rise and brighten the Earth for me,
In the days when my power has gone."

He passed to the South and, behind him,
Stern Winter arose and frowned;
Cried he "This rule of the Sun shall cease,
My joy is a barren ground!"

So he tore the leaves from the branches,
Rolled his mists like a shroud of death,
And all the air of the garden
He chilled with his icy breath.

Then the flowers which slept in the summer
Felt the touch of his hand and awoke;
The Hellebore and the Snowdrop,
The Cyclamen under the Oak.

Then, through the gloom of the woodland,
Shone the Witch Hazel's light,
And each of the barren branches gleamed
With crystal jewels bright.

When Winter saw his forces
By Beauty thus beguiled,
His harsher mood was melted,
His brow relaxed—he smiled.

A. E. SIMS

ERIGERON MUCRONATUS.

THERE is some excuse for making mistakes about the proper name of the above plant (see pages 500 and 597). Vilmorin of Paris, in his book "Hardy Flowers," first edition, page 950, mentioned a plant which he called *Vittadinia lobata*, which the "Index Kewensis" named *Vittadinia australis* with a query to indicate doubt. Stendel spelt the name *Vittadenia*, which was wrong. Whether the confusion of names originated in Paris or not, it is certain that *Erigeron mucronatus* was confused with *Vittadinia* under the name of *V. triloba* in this country in 1880. I have seen it in a dictionary under its proper name, with *Vittadinia trilobata* as a synonym. *Erigeron mucronatus* is a native of Mexico. *Vittadinia australis* in the flora of New Zealand has white rays to the heads; but the species is also a native of Australia and Tasmania, where it runs into numerous varieties. Three of these described varieties have become naturalised in the South Island of New Zealand, and all of them have purple ray-florets besides other distinctions. *Erigeron mucronatus* and *Vittadinia australis* in their typical form have some considerable resemblance outwardly, and are separated generically by minute but important particulars in that large and complicated Order of plants, the Compositæ.—HORTULANUS.

FLOWERING SHRUBS FOR WALLS AND HEDGES

EVEN in the south of England the cultivator is justified in planting certain choice flowering shrubs so that their branches may be trained on walls. In the midland and northern counties the protection afforded by a wall is essential for the satisfactory growth of some kinds.

Where inner hedges are necessary, more for screens than resistance, there is much to be said in favour of those composed of flowering plants. The necessary pruning to keep the plants within reasonable bounds may be carried out without interfering very much with their flowering from year to year.

It often happens that walls selected for covering plants are backed by tall trees or shrubs, whose roots permeate the soil under the wall and beyond

With regard to hedges I am not including Roses in this note, though suitable varieties are always welcome where they can be grown as hedge plants. The China Rose, the Austrian Briar, the hybrid Sweetbriar, all are charming, and not least the common Sweetbriar.

EVERGREEN PLANTS FOR WALLS.

Azara lanceolata, *A. microphylla*, *Berberis stenophylla*, *B. racemosa variegata*, *Buddleia globosa*, *Ceanothus dentatus*, *C. floribundus*, *C. Veitchianus*, *Choisya ternata*, *Cotoneaster buxifolia*, *C. horizontalis*, *C. rupestris*, *Crataegus Pyracantha*, *C. P. Lalandei*, *Eleagnus pungens*, *E. glabra*, *E. pungens Simoni*, *Escallonia langleyensis*, *E. macrantha Ingrami*, *E. montevidensis*, *Forsythia suspensa*, *Fremontia californica*, *Garrya Thureti*,

THE MEXICAN ORANGE, CHOISYA TERNATA AGAINST A WALL.

to a considerable distance. Where this is the case such roots must be cut out before any planting of wall plants is done. Slates, on edge, should then be fixed clear of the wall foundation, the original soil be replaced and some good loam be placed on top for the benefit of the wall plants. The roots of the larger trees will again push into the soil, but, for several years, below the new loam. When, at length, they take possession of the prepared compost, light annual top-dressings will sustain the wall trees. Where there are no large trees near enough for their roots to reach those of the shrubs, very little labour will be necessary in preparing the border near the wall.

SUITABLE PLANTS FOR VARIOUS POSITIONS.

The cultivator should give due thought to this matter. It is always very unsatisfactory when strong-growing plants are trained on quite low walls; their proper place is one where there is ample space both for their roots and branches. Compact and possibly somewhat slow-growing plants are best for low walls.

Griselinia littoralis, *Magnolia grandiflora* (for high walls), *Myrtus communis*, *Olea fragrans*, *Pittosporum eugenioides*, *P. variegatum*, and *Piptanthus nepalensis*.

DECIDUOUS PLANTS FOR WALLS.

Ceanothus azureus, *C. Gloire de Versailles*, *Cydona japonica*, *C. j. rosea*, *C. Maulei*, *Desmodium penduliflorum*, *Hydrangea quercifolia*, *Indigofera Gerardiana*, *Lospedeza bicolor*, *Lycium europæum*, *Punica Granatum* (single), *P. G. flore pleno*, *Rubus deliciosus*, *Solanum crispum*, *Viburnum plicatum*. Where much wall space is to be furnished a few non-flowering plants, possessing lovely foliage, judiciously mixed with the majority, will help to set off the beauty of the latter.

A collection of Mock Oranges and *Hibiscus syriacus* will form a very charming hedge or screen fence between the flower garden and vegetable ground, especially so if there are a number of evergreen flowering shrubs dotted in a few feet apart immediately in front of it. The use of hardy Fuchsias for this purpose is also practised. G. G.

EVELYN'S KALENDARIVM

ONE of the Englishmen of the past whom I admire above others is John Evelyn. He was such a real gentleman, and his "Sylva" and his "Kalendarium" go far to prove it. They are abiding testimonies for all time of his thought for his country and his fellows. Poor England denuded of the wherewithal to fashion anew her wooden walls! No League of Nations in sight! The fear of the Great Armada from Spain still fresh in men's memories! And then came Evelyn with his "Sylva"—an altogether unconventional example of the pen being mightier than the sword. Fortunate England! his "tongue was the pen of a ready writer." Who can measure or compute how much "This precious stone set in the silver sea" owes to his "Sylva"? We are going to dry-dock the old Victory. Will none of our great lovers of their country statesmen take measures to dry-dock in some public place, where he "that runs may read," this simple book and place upon its case some legend after this manner. "No Evelyn, no Nelson: no 'Sylva,' no Victory." Then this "Kalendarium," if one may compare small things with great. If Humphrey Davy's, comparatively speaking, small invention of the miner's safety-lamp may be placed side by side with his much greater work, and by some be judged of even higher merit because it was the visible sign of a much distressed heart in one who knew full well the dangers of the mines; may we not in some such way compare these two books of this famous Squire and say that if the first, the larger and the more important one compels our admiration, the second, the smaller and the less known creates in all of us gardeners who know but too well their limitations, a fellow feeling, nay a personal love to think that he thought for beginners, for the ignorant and the forgetful, and compiled out of his vast store of gardening knowledge a simple little book which he hoped would be for many years their guide, philosopher and friend. We all know how true is the lesson which Virgil teaches in his first *Georgic* and which our author includes in his preface:

"Gard'ners had need each Star as well to know,
The Kid, the Dragon, and Arcturus too,
As Sea men, who through dismal storms are wont
To pass the Oyster-breeding Hellespont."

The illustration had more point, naturally, in 1666 than it would have had, had the "Kalendarium" been one of the new books of 1922. It must be remembered that Evelyn himself is not wholly free from astrological domination—under October's work to be done in the orchard and olivory-garden we read "Moon now decreasing, gather winter fruit that remains"—and secondly, that a good practical florist like Samuel Gilbert, the son-in-law of John Rea appended to his first edition of his "Florist's Vademecum," published in 1682, a *kalendar* or, as he calls it, "The Gardener's Almanack," for

the years 1683 to 1687, showing among other details "The Sun and Moon's Place each day in the Signe," which, if the advice given in the sort of preface with which the little book opens is to be followed, are absolutely necessary. How else would it be possible to dress your gardens and trim your small trees and shrubs "when the Moon is in Libra or Capricorn"? In this same introduction we seem to get a hint of the origin of this (to us) strange and fanciful astrological theory. There would be every likelihood, considering the feeling of mediæval times, that as with the Doctrine of Signatures it

THE TITLE PAGE OF THE KALENDARIVM HORTENSE.

should have had a Biblical or religious origin, and it seems to be quite in the nature of things that there would be a wish to put into practice the saying of Solomon "That to every thing there is a season, and a time to every purpose under the heavens; a time to plant, and a time to pluck up that which is planted." Might it not be attained by a careful study of the position and state of the moon? Even an Evelyn cannot wholly divest himself of the popularly accepted theories of his time, any more than an up-to-date country practitioner can resist the popular "You must have your teeth out" advice of to-day. I saw it recently "in the paper" (but no certificate of authenticity accompanied the statement) that a tennis player had been ordered this treatment for a sprained ankle! Thus to know that this famous man kept an eye upon the moon only makes him more human, and by no means prejudices us against, nay rather gives

us a bias in favour of, this splendid little book. It was the sympathetic spirit and the keen eye of John Evelyn that made him realise so clearly the "extreme perplexity, which for want of a constant and uniform Method does so universally distract the vulgar (or as we should now say, ordinary) sort of Gardeners." How he met it is disclosed in the "Kalendarium." The method was not altogether new. In all probability he got the idea from others, and among them from our own Thomas Tusser, who in his "Five Hundred Points of Good Husbandry" had many years before included something of the housewife's work in the garden in his monthly directions about the ordering of a country farm, Evelyn developed this, and by developing it may be said to have made it in his "Kalendarium." It is the high-water mark in the history of the art and practise of gardening; and every editor of a gardening paper in the present year of Our Lord, 1922, still feels its necessity inasmuch as he devotes a no inconsiderable space in every issue to "Gardening of the Week," or "The Week's Work," or an article with a similar title, all of which in their essence and intention are but the "Kalendarium" writ large and brought up to date. Just for a moment, ye modern columns, look at the rock whence ye have been hewn and at the hole of the pit whence ye have been digged. The *The Eocene stratum* is Evelyn; then there is Philip Miller; newer still comes John Abercrombie; then almost last of all, Joseph Paxton. These are the great broad layers deposited by time; and careful inspection finds that between them are the thinner lines of other deposits—here continuous, there broken—perchance a Bradley, a Whitmill, a Justice, a Reid or a Lawrence, but altogether forming that solid mass on which there is now accumulating a far deeper layer than any of them, viz., that being formed by the long series of "what-must-be-done-weekly" articles contributed through the medium of the gardening press by many of the very front-rankers of our time. I have met so many garden lovers who think these week's-work columns are about the most important part of a paper that a glance at their evolution may not be unacceptable; and I am prepared to put my back to the wall and stand up to those who would say that such writing is not practical.

What is "Practical"? Why should this hackneyed word be confined to the telling people how to plant and what to sow; how to cultivate and what to buy? Is there nothing "practical" necessary to equip the purely literary gardener? I call to mind as I write two of my friends—both welcome contributors to this paper, one of whom lives in a lovely garden within an easy motor run of our Northern capital, and the other in the far less beautiful surroundings of a London suburb, whose name is thinly veiled by calling it Dogbridge, to whom history is as the breath of life. Anything that adds to their stock of knowledge surely may be called practical. It is a different practical, of course to the being told how to dig, and plant, and sow, and alas! some do not seem to recognise it. Quite so. As Mrs. Browning puts it, "Its only he who sees takes off his shoes." When, however, we come to think of the contents of the "Kalendarium" we are on somewhat different ground. I put it like this. Suppose on a single day these three entertainments were to be advertised: the very best Charlie Chaplin film, the football Cup Final, and a sort of spiritualistic séance which would show each one his home and the places he knows best century by century right through the past, let us say, until the dawn of the Christian era, would not the biggest crowd be at the last named? The gardener, too, must wish to know what gardening was like at different periods of the past, and where can he get a better idea of it than in studying such a very practical book as the one which has set alight this

present article. I would like to take a leaf out of "The Charm of Gardens," and copy Dion Calthrop by quoting the entire work, but decency forbids— I have to think of our editor and my readers, some of whom might wish it at Jericho, as I would do myself were I to come across it in a weekly gardening paper—I hope, however, a very few extracts may not be unacceptable, when we remember upon how high a pinnacle Evelyn himself placed this little book when on the title page of his "Acetaria" he described himself not as might reasonably be expected, as author of "Sylva," but as author of the "Kalendarium Hortense"; and when we remember, too, the deliberate opinion of Cowley, who thus describes it: "The most useful Book that has been written in that kind, and which is to last as long as Months and Years." In this and in the majority of these old Kalendars we get sub-sections every month with some such headings as "Fruits in prime, and yet lasting," "Flowers in prime, and yet lasting" (Evelyn), the idea of which might usefully be revived. Such lists are very useful; but they seem to have dropped out.

In vain do we seek them in "The Calendar of Garden Operations" (1920), which is Paxton's in modern dress; or in our weeklies in the week's-work columns; and yet it seems to me just as necessary to know when an Apple will be in perfection for eating as to be told when to plant it; and to visualise the flowering of July as to know when to sow the seed. Then the importance of bees in those old days was far greater than it is now. Month by month Evelyn has a short paragraph about them. In September he writes: "No longer defer the taking of your Bees, strengthening the entrances of such hives as you leave to a small passage."

We get a peep at garden practice under September, he suggests the origin of our familiar word, greenhouse: "About Michaelmas (sooner or later as the season directs), the weather fair, and by no means foggy, retire your choice Greens and rarest Plants (being dry) as Oranges, Lemmons, Indian and Spanish Jasmine, Oleanders, Barba Jovis, Anonum Plin, Citysus Lunatus, Chamelaea tricocos, &c., &c." What a difference in the advice about Strawberries; now it would very likely be "Get some from Laxton Brothers of Bedford"; then it was "Plant Strawberries out of the Woods," just as it had been in the time of Tusser nearly a century before.

"Wife into thy garden, and set me a plot,
With strawberry roots, of the best to be got;
Such growing abroad, among thorns in the wood,
Well chosen and picked, prove excellent good."
(September's Husbandry in "Five Hundred Points of Good Husbandry.")

This is a curious bit under November: "Take up your Potatoes for winter spending; there will enough remain for Stock, though never so exactly gathered." It is clear "seed" from Scotland was not then contemplated. Earwigs must have troubled Evelyn's Nectarines rather badly. His denunciation is quite scriptural in its vehemence and wording, "They are cursed Devourers," he says. At the bottom of the same page in my edition (the eighth, page 85) he gives a bit of advice which we all should do well to follow when we are troubled by the unwanted visits of biting animals and which I find as true of flowers as of fruit. "Pull not off what is bitten; for then they will certainly begin afresh." It is difficult to stop, there are so many little tit-bits in the book. Perhaps some readers will think it worth while from what has now been extracted, to get the book themselves and enjoy it at leisure with a pipe in their own easy chair. *Sic Volo.*

JOSLPH JACOB.

THE CREEPING COTONEASTERS

THE members of the genus *Cotoneaster* which are prostrate, or nearly so, in habit comprise an interesting group: they are extremely useful in gardens and their ornamental value is not the least of their good points. They are all perfectly hardy, they will thrive in almost any kind of soil, in sun or shade, and they do not object to tree drip. Rapidity of growth is another attribute common to most of these *Cotoneasters* and one that is particularly essential in a class of shrub which is so often planted for the express purpose of quickly covering ugly rock faces and walls, untidy, stony corners, the ground beneath specimen trees and other places of the sort. Some of these species, in addition to possessing an attractive foliage and habit, bear a crop of brightly coloured berries, and all are plants which are adaptable for the smallest as well as the largest garden. Propagation is simplicity itself, for one has but to layer the creeping branches to provide plenty of rooted bits. In fact most kinds make their own layers naturally.

One of the most taking of these prostrate *Cotoneasters* is *C. adpressa*, a comparatively newcomer from China, but one which has rapidly become a favourite with rock gardeners and others owing to the pretty manner in which it will creep over a rock face, the fish-bone branches closely hugging every irregularity of the surface. This is a robust and fast grower, with a bright green, glossy foliage, which turns a deep red before the leaves fall in autumn. It flowers early, the blossoms being much like those of *C. horizontalis*, and the scarlet berries are ripe by August. If for some purposes the deciduous nature of *C. adpressa* may be considered a misfortune, the fact remains that were it an evergreen we should not have the autumn colouring nor the beautiful fresh spring green of the opening leaves, which is one of the most charming features of the shrub. Indeed, *C. adpressa* possesses all the excellent attributes of *C. horizontalis*, of which it might be deemed a miniature.

The evergreen Himalayan, *C. congesta* (*nummularia*), said to be a form of *microphylla*, viz., *C. m. gracialis*, is another of the indispensables and a most delightful shrub, with ruddy, often claret-coloured stems and comparatively large leaves of a soft and pleasing green. This is a first-rate plant for rambling over bold rockwork or for covering sloping banks and it will do equally well for carpeting on the flat. We have it growing among *Erica carnea* with good effect, the branches arching in characteristic manner as they weave their way through the Heath. The result is pleasing at all seasons, though it must be admitted that *C. congesta* does not berry so freely with us as the other kinds do. There appears to be an infinite variety of forms of *C. congesta*, or perhaps it would be nearer the truth to say that this shrub will materially alter its manner of growth in accordance with its position, aspect and other influences, not always easy to define. Thus it may be seen as quite a small-leaved shrub, clinging like Thyme to a rock and yet a few yards away, as in Mr. Buxton's fine garden at Bettws-y-Coed, it will rise up into a conical mound 4ft. to 5ft. in height and as symmetrical as if it had been sheared by a topiarist.

Like *congesta*, the allied *C. microphylla* can be used in all manner of ways. Though so often seen as a covering for cottage walls, it is, I think, more pleasing as a carpeter or when allowed naturally to mound into a low bush. The small, glossy foliage is beautiful at all seasons. The plant is a profuse bloomer and, like most others

of its race, is very attractive to bees, wasps and flies when the flowers open in spring. We grow it also on Heath banks and the fine crop of fruits it almost invariably bears, the berries being of a peculiarly high-toned chalky pink, is usually carried through the greater part of the winter. *C. microphylla* is indifferent as to aspect and does well in shade, but full exposure is essential to free berrying. Though so common everywhere, this is still one of the best *Cotoneasters* of its class. It also is liable to "sport" curious aberrations from the type.

C. thymæfolia might be described as a dwarf form of *microphylla*, but its evergreen leaves (the smallest of the family) are more oblong in shape and the young wood is more distinctly silky before it assumes the ruddy gloss of maturity. This is a close grower, admirable for the small rock garden, and while the shining, deep green foliage, which will make a dense mat, is refreshing at all seasons, the little creeping branches produce pretty pinky flowers, followed by scarlet berries. Though also a Himalayan species *C. thymæfolia* is apparently quite hardy.

Another very prostrate evergreen species, not unlike the foregoing in habit, is *C. pyrenaica*. But the leaves of this one are larger and hardly so thick and leathery as are those of *thymæfolia*, being more akin to those of *congesta*. Indeed, there seems to be no little difference of opinion among nurserymen as to what *C. pyrenaica* really is, forms of *congesta* and *thymæfolia* being sometimes sent out under its name. *C. rupestris*, often listed as a creeping kind, is a strong-growing, deciduous species more after the style of *horizontalis*, but with more horizontal "planes"— unless I also am fostering a case of "mistaken identity," almost unavoidable in this confusing race.

There can, however, be no mistake about *C. humifusa* (*Dammeri radicans*), for this is entirely distinct from any other, a perfectly flat, creeping plant, whose long trailing stems seldom rise more than an inch or so above the ground or the rock face which they so elegantly drape. The large, willow-like leaves are partly deciduous, those which are shed assuming brilliant autumn colours. *C. humifusa* flowers in summer, the little white or pinky-white flowers being held erect on short stems which rise clear above the prostrate branches. These are followed by crimson fruits which, if the mice spare them, usually remain until winter. This species is one well worthy of a good place. It should be given at least a couple of square yards, in sun or half shade, and it is seen to best advantage when grown on about the level of the eye.

Several new evergreen or sub-evergreen *Cotoneasters* have been introduced of recent years, mainly from China, most of which are still, I believe, nameless. One of these growing here might be described as a dwarf form of *C. horizontalis*, but with semi-deciduous foliage, and another appears to be wholly evergreen, the comparatively large, glossy leaves as well as the habit being, to the average observer, identical with *C. prostrata*, as listed by the trade.

C. praecox is one of the most distinct of the more recent novelties, a strong-growing shrub which proceeds with a creeping and arching habit over a considerable space, promising eventually to make a low mound. The leafage, which is deciduous, is larger than is that of *congesta*, a fine, rich ivy-green and highly burnished, but it has not, thus far, given us such fine autumn colour as *horizontalis* usually does. *C. praecox* is so called from its habit of fruiting early, the berries, as

large as peas and in a striking crimson, being ripe in July.

I have referred to the confusion which exists regarding the identity or naming of many *Cotoneasters* by nurserymen, but while those who compile trade lists may perhaps be pardoned for making errors where "doctors disagree," many such irregularities might be avoided. For example, I have before me a catalogue issued by one of the foremost nurserymen in this country. In it

CC. horizontalis and *houpinensis* are given as *evergreens*. In another list of an equally reputable firm, *C. adpressa* is also listed in the evergreen section. As the trade catalogues generally are so helpful to amateur gardeners, it seems a pity that such obvious slips should be made, and I take this opportunity of suggesting that a little more accuracy would be an inestimable boon to those for whom the catalogues are mainly intended—the struggling novices. A. T. J.

Beds of Sage may also receive some stimulating manure at this time, forking it lightly in between the rows. These little attentions are necessary where well grown herbs are desired and, if done now, considerably facilitate the carrying out of other work during the spring months.

The Hardy Fruit Garden.

Loganberries.—Cut away all the old growths of these and tie in the quantity necessary for furnishing the poles for next season's fruiting. Where the planting of these is contemplated, the grower would be well advised to choose a part where their rampant growth will have full scope. The rougher or outer portion of the garden suits this strong-growing Bramble admirably.

Cleansing Fruit Trees.—The important work of winter spraying fruit trees should be preceded with immediately the pruning in the various parts of the garden is completed. Where a large number of trees have to be dealt with, a knapsack sprayer proves more economical and effective than an ordinary syringe. A calm day should be chosen for carrying out the work. Among the many preparations recommended for the winter spraying of fruit trees, we find none more suitable than Bentley's Concentrated Alkali, as it destroys moss and lichen as well as the many insect pests harbouring in the crevices.

The Pleasure Grounds.

Protecting Tender Shrubs.—Now that severe frosts are imminent, the more tender plants in the shrubbery or on walls or trellises should receive a certain measure of protection. This is especially advisable in the case of small or newly planted specimens. Feathery spruce branches are most useful for the purpose of sheltering the plants, while bracken is also of value for tying round the small-growing sorts.

Planting Hedges.—Various sorts of hedges may now be planted, using discretion in the choice, according to the site and utility of the hedge. For boundary hedges Thorn and Beech are best, while for a quick-growing screen, Privet and *Thuja Lobbi* are popular. Holly, Yew and Box also provide desirable evergreen divisions or shelters in the pleasure grounds.

Magnolia stellata.—This beautiful Japanese shrub should be planted now, as it flowers during April and provides a most pleasurable sight with its mass of waxy white blossoms. It is of undoubted hardiness and is of close and compact habit, being exceedingly floriferous and proving, with us, to be the most satisfactory of the *Magnolias* planted in the open. JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Bouvardias as they pass out of flower should be removed from the greenhouse and stood in a dry, airy house, where a temperature of 40° to 45° can be maintained. The plants should be kept dry at the roots for several weeks and towards the end of January should be partially pruned back and removed to a warm, moist propagating house, where, if given water at the root, they will soon start into growth. When the young shoots are about 3 ins. long they should be removed for cuttings, for at this stage they root readily in a warm propagating case. Many cultivators complain that *Bouvardias* are difficult to propagate, but their failures are usually due to using too old wood for cuttings. If young growths are used there is no difficulty in rooting them. *Bouvardias* may also be propagated by means of root cuttings; old plants are best for this purpose. They should be turned out of their pots and all the soil shaken away from the roots; select some of the thickest roots and cut them into pieces about 1 in. in length. They should then be placed in pans or boxes of sandy soil and if stood in a warm propagating case they will soon start into growth. Some growers contend that root cuttings make the best plants; personally I have never been able to detect any difference between them. It must be remembered that all varieties of *Bouvardia* do not come true from root cuttings. The variety *Bridesmaid*, for example, when propagated by means of root cuttings, always gives a proportion of *Hogarth* fl. pl. *Bouvardias* are so beautiful and useful that it is a pity their cultivation is so generally neglected at the present day. They are very subject to attacks of *Begonia mite*, which can be prevented by the use of Campbell's sulphur vaporiser. During the last few years white fly has proved very troublesome and this pest may be kept in check by the various remedies that are in general use. Fumigating with sodium cyanide

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Celery.—It will be advisable to have means of protection ready for immediate use for the onset of the Celery crop during a sharp spell of frost. Failing any permanent covering, made of boards or other material, it will be enough liberally to strew some dry straw or bracken fern over each row, taking care always to remove the same when the frosty period breaks. Although Celery is better left in the ground when possible, a week or ten days supply should be lifted upon the approach of a severe spell of frost and kept fresh and in good condition by heeling in the sticks deeply in soil in an unused frame or close to a wall.

Parsley is so indispensable to the kitchen that no effort should be spared to keep up a regular supply. It has so far been easy to make good pickings from outside without giving the plants any protection. From now onwards, however, some shelter should be afforded the crop. A simple way of giving such protection is to drive in stakes of suitable length along the rows or bed and stretch strands of wire to connect them all, over which it is an easy matter to place canvas or matting.

Peas and Beans.—Autumn sown crops that are now nicely through the soil may receive protection by having the soil drawn up in ridges on each side of the row. Keep a look-out for slugs and mice.

The Flower Garden.

Hardy Ferns.—Should the weather be open and favourable, planting may be done now or it may be postponed until spring. When preparing a fresh site for a colony of these plants, liberal supplies of old leaf-soil and common peat should be employed. It may be necessary, for the sake of appearance, to cut away the old yellowing fronds of established Ferns in some parts of the garden at this season of the year, but they should always be left if possible, as they are of great help later on in warding off cold winds, etc., from the young fronds. All leaves which have accumulated among the plants should be allowed to remain until spring, when, if sufficiently decayed, they may, with great advantage to the plants, be forked into the ground or have some old soil thrown over them, thus making a good mulch and adding to this just such rooting medium as the plants appreciate.

Lawns lacking in vigour will derive great benefit from a good dressing of well rotted manure, leaf-soil and good loam. Mix the whole well together and pass through a coarse sieve before spreading evenly over the lawn where required, to a depth of a couple of inches, the compost being occasionally raked over during winter. Lawns requiring no such treatment should have an occasional sweeping and rolling, the latter being particularly beneficial on light soil.

The Hardy Fruit Garden.

Basic Slag.—This is recognised as a useful phosphatic manure for all fruit trees, particularly those cultivated on heavy land. Being somewhat slow of action, it is a good plan to apply it during the autumn months, so that it may filter gradually into the soil during the winter. It may be spread fairly liberally over the ground covered by the head of each tree or bush dealt with.

Vines.—The necessary pruning of these can be done now, unless the weather is very frosty, when it is not advisable to prune, which, indeed, applies to any other kind of fruit. Spur closely in unless wood is required for extension or is being encouraged to develop so that it may replace exhausted portions, in which case the young growths, if thoroughly ripened, may be left from 1 ft. to 3 ft. in length. Nothing is gained by having spurs or rods too close together.

Fruits Under Glass.

Late Grapes.—Nothing will be gained by allowing these to hang longer on the vines, so they should be cut and taken to the grape-room or wherever they are to be stored. The great point about the storage quarters is that an even temperature must be aimed at, and the light should be excluded. As a general guide, if a temperature of 45° to 50° is regularly maintained, the bottles kept replenished, as necessary, with water, and all decaying berries immediately removed, there will be little cause for worry about them keeping, always providing, of course, the Grapes are in a fit condition to commence with.

Vine Borders which extend outside the house are better if given some measure of protection from excessive rain and snow. It is not so important for the borders belonging to mid-season Vines, but applies particularly where there is an outside border belonging to the early house. A suitable covering may be made by placing a good depth of newly gathered beech or oak leaves, then a layer of straw to hold them in position and then over both place some boards or sheets of corrugated roofing, arranging them so that the rain will be carried away from the border.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Gardens.

Cucumbers.—Where well heated pits are available for forcing purposes a sowing may now be made of a free setting and quickly maturing variety. Sow singly in 2½ in. pots and plunge the pots to the rim in fibre or sand in the warmest corner of the stove or pit. Care must be taken that the seedlings are never subjected to a sudden check by the lowering of the temperature, or chilled by the injudicious use of the watering-can. When watering is necessary see that the water is of sufficient warmth to have no ill-effect on the young plants. Varieties such as Blair's Prolific and Veitch's Sensation have proved reliable sorts for forcing during the winter and spring months.

Salads.—Continue to sow Mustard and Cress in boxes at intervals so that a continuous supply of tender growths may be maintained. Lettuce in frames should also be looked over and growth encouraged, ventilating freely so that damp may be checked.

Autumn Sown Onions.—In many gardens the autumn sown crop has been making extra growth owing to the lengthy spell of mild weather experienced during late October and November. Break the surface soil between the rows and give a good surface dressing of wood ash. The soft growths of young Onions are at times more readily damaged by cutting winds than by severe frost, so that it is beneficial to place a few wattle hurdles or spruce branches in position to shelter the crop.

General Work.—Continue to clear the ground of spent crops and tidy up the vegetable quarters in preparation for the further carrying out of digging or trenching operations. Cabbage leaves, soft weeds or other quick rotting material may be buried in the trench. Add leaf-mould to heavy land whenever such is available as this proves a valuable substance to assist in the lightning process. Old hot-bed manure in which leaves predominate is also excellent for this purpose.

Herbs.—The herb border should also receive some little attention at this time, cutting over the withered foliage and leaving the beds clean and clear of weeds. Mint being to a large extent surface rooting, derives much benefit from a surface dressing of leaf-mould or old potting soil.

is most effective, but it is so dangerous that one does not care to advise its general use.

Hydrangeas that were propagated during the summer and have been standing in cold frames exposed to the weather, should now be ready for forcing. For this purpose plants with strong forward buds should be selected. When first taken indoors they should not be placed in too high a temperature, 40° to 45° being high enough for a few weeks, after which it may be increased to 55° or 60°. Hydrangeas, when growing, enjoy copious supplies of water at the roots, but when taken indoors at this time they are more or less at rest, thus watering should be carefully done until the plants are in active growth, when the supply may be increased. When in full growth the plants will benefit by frequent applications of diluted liquid manure or soot water. Large specimen plants stored for the winter should not be allowed to become over dry and should be examined occasionally. Blue Hydrangeas are usually in favour and there are various methods, more or less successful, of imparting the desired colour. Alum and iron filings are frequently used, but it does not always follow that they will produce the desired effect, the colour often being an ugly reddish purple. This is probably often due to the treatment not being started early enough, and no doubt water plays an important part, and it is well always to use rain-water. In recent years there have been several proprietary preparations that are successfully used by trade growers to impart the desired blue colour. If any such substances are used the treatment should be started with the young plants and should be used regularly until they flower. Only the pink-flowered varieties respond to the treatment.

Plants for Forcing. according to requirements, should be introduced to suitable houses, remembering always to start them gradually, as too high a temperature at first is apt to result in failure, bulbous plants going what is known as "blind," while shrubby plants often drop their buds.

Freesias that were potted up early should now be well advanced, and should be removed from the cold frames to a light airy greenhouse. The plants should be kept carefully supported, for the growths, if allowed to fall over, never properly recover. When in full growth Freesias enjoy frequent applications of diluted farmyard manure or soot water.

Hippeastrums.—Where early flowers are required a batch of plants should be placed in a warm house and if they can be plunged in a warm bed they will develop quicker. For this purpose bulbs that were started early last year should be selected as they, of course, finished their growth early and having had longer rest will more readily start into growth. It is also important to select plants that are in good condition at the root, as they suffer no disturbance from repotting and start away much quicker than newly potted plants. To my mind they have an added charm as they develop their foliage along with the flowers. The plants should be thoroughly soaked at the root, turned out of their pots and the drainage corrected if necessary. Some of the surface soil should be removed and replaced with a top-dressing of good loam, to which a little leaf-soil and coarse clean sand has been added, also a 6in. potful of fine bone meal to every bushel of soil. Very little water is necessary at the root until the plants are in active growth. J. COVETTS.

Royal Botanic Gardens, Kew.

The Sloe or Blackthorn. In the desire to have in our gardens the choicest exotic trees and shrubs the best of our native British flora must not be overlooked. Among these is the Blackthorn of our hedges and coppices, *Prunus spinosa*, of which the leafless black branches are whitened with snowy blossoms in March and April. A small tree or large shrub, the Sloe spreads by means of suckers and is also raised from seeds. An important consideration is that trees growing in poor soil usually flower more freely than in deeply cultivated rich ground. Equally or even more valuable for the shrubbery border is the double-flowered variety, *flore pleno*. This is usually propagated by budding, using the Plum as a stock.

The Valerian. A word or two should be said in praise of the Valerian, *Centranthus ruber*, at this season, when most of us are

thinking about the spring planting of perennials. We do not see it in gardens nearly as often as we should, the popular idea being that it is a strong-growing weed and unworthy of a place. Splendid effects may be produced if it is planted towards the top of a very dry wall garden, or planted on the boundaries of shrubberies where little else will grow. Its floriferous nature (for it gives masses of bright red flowers all through the summer) and the easiness of its cultivation make it a most desirable town garden plant, and so long as it is not permitted to seed itself and is lifted and divided every two years, it can easily be kept within bounds. Its height is somewhat variable, ranging from 1½ feet to 3½ feet. The second year it forms fine "bushes," which look neat and bright in the mixed border.

A Quaint Iridaceous Plant.—*Aristea corymbosa* is an August-flowering greenhouse shrub with flowers of a beautiful clear blue (Tone I, series 211, in the "Répertoire des Couleurs"). It is botanically interesting as being the only member of the Iridaceæ having secondary thickening. The short woody stem is apparently an upright replica of a rhizome, roots being produced from the younger regions of it at two distinct periods—early in the year and again in July, when the flower-spikes push. This periodic rooting habit is repeated in the cuttings; they callus fairly easily, but only produce roots at the same moment as the parent plant.

Staphylea colchica.—A pretty shrub that should be in every garden. The drooping terminal clusters of cream white bloom come in May with the Lilacs, a little in advance of the Gelder Roses. Though it is quite hardy, it likes a sheltered place and does not object to a little shade. Prepared plants are often used for forcing.

R.H.S. Gardeners' Diary.—We have received a copy of this excellent pocket diary for 1923 which reflects credit alike on Editor—Mr. W. R. Dykes—and the publishers. The make-up of the book is similar to previous years and there is as much daily space as is usually afforded in a pocket diary. An opening of the book (two facing pages) is devoted to each week's work and advantage is taken of the space which would accommodate another day to include, in this most convenient place, a summary of the week's work. An immense amount of incidental information is included on other pages, ranging from "Alpines, Seeds of," to "Worms on Lawns," and including *en route* "Scotch Moorland Berries," the whole being efficiently indexed. As the price is only 2s.—no more than one needs must pay for an ordinary diary—no gardener should be without one.

ANSWERS TO CORRESPONDENTS

THE FRUIT GARDEN.

CURRANTS AND STRAWBERRIES FOR NORTHERN DISTRICTS (C. F. S., Bannockburn).—Red Currant Ruby Castle and Strawberry Royal Sovereign would answer our correspondent's purpose. Both kinds are hardy, prolific, strong-growing and of high-class flavour.

DIGGING NEAR FRUIT TREES (G. P. T.).—The soil under fruit trees should be kept clean—free from weeds and injurious insects. To ensure this the surface soil must be loosened with the Dutch hoe or the garden fork. Furthermore, the work must be done carefully so that the fibrous roots are not broken off. Digging or disturbing the soil any deeper than is necessary to accomplish the purpose named, and to ventilate it, would prove injurious. A spade must not be used, as the blade would cut off roots without the workman being aware of it. Only in exceptional cases should grass be allowed to grow under fruit trees. Even in grass orchards a space several feet from the stem should be free from grass.

THE GREENHOUSE.

VERONICA PLUCKEANA (F. G. P.).—When the plants have flowered place them outside in a sheltered position, not in a very hot one at first. Apply clear water carefully; if much pot-bound, re-pot the plants directly new shoots grow, when pricking is advisable wait till the young shoots are 1in. to 2ins. long before re-potting. Loam two-thirds and peat one-third make a suitable compost. Pot firmly and be very careful about watering afterwards. While new growth is being made the plants must be in a quite open position and remain there till September. The winter greenhouse temperature should range from 40° to 45°. Propagate cuttings when available late in spring or early in summer in a similar compost and sand added, under a bell-glass or frame.

CHRYSANTHEMUMS ATTACKED (D. W., Surrey).—The Chrysanthemums attacked by the leaf-mining maggot should be sprayed with a nicotine wash which will kill the larvae boring in the leaf. Where only a few are concerned they may be killed in their burrows by pinching between finger and thumb. Spraying plants with paraffin emulsion or dusting with soot are excellent preventives.

KITCHEN GARDEN.

ABOUT SOWING PARSNIP SEEDS (T. L.).—In a very light, sandy soil the seeds may be sown at this early date and the resultant roots grown to a large size. In heavy, retentive soils the majority of the seeds would rot, especially if a spell of wet weather came. It would be much the best if our correspondent trenched, or deeply dug the soil now and prepared it thoroughly for the seeds at the end of January. As the ground is clayey this treatment would ensure the best results.

THE CHINESE ARTICHOKE (A. J. M.).—This artichoke (*Stachys tuberosa*) is not extensively grown now; for some years after its first introduction it was. The roots are spiral in form, an average size of one being 2ins. long and ¾in. across the centre—the thickest part. The roots should be planted in March, 1ft. apart in rows 2ft. asunder. Any ordinary garden soil will be suitable, especially that manured the previous autumn. The plants increase and spread in the soil very rapidly, yielding tubers in abundance. They should be boiled till tender, not pulpy, then lightly fried in boiling fat till nicely browned and, after draining, served hot.

CLUB-ROOT (F. H., Wimbledon).—Dress again with ground chalk lime at the rate of 1 bushel to the square rod, but do not plant any Brassicas for a year. Gas lime is useless. Manure may be applied to the Rhubarb any time now and in February cover the roots to blanch the young growths. Litter of dead leaves about the boxes will hasten growth in spring.

MISCELLANEOUS.

NAMES OF PLANTS.—J. C., Shrewsbury.—1, *Cratægus Pyracantha*; 2, *Veltheimia viridifolia*.

PERENNIAL PLANTS FROM SEED

(Continued from page 640.)

THE Foxglove, *Digitalis purpurea*, is one of those "shaky" perennials which wise folk treat strictly as a biennial and either raise regularly from seeds or allow a few spikes of the best forms to remain and seed themselves. There are very few people who can so arrange plants as to produce the natural effect which self-sown seedlings always give. There are many who prefer the newer spotted forms to the typical hedgerow plant, but, somehow, the florist has been less successful with the Foxglove than with most plants he has taken in hand and beyond a variation in the spotting and a certain paling of the rich colouring of the typical plant, he has achieved nothing. The admirable white form he cannot claim, as it is fairly common among wild plants. This white form is an excellent border plant, but is really seen to best advantage in thin woodland.

All perennial Poppies are readily raised from seeds, indeed, some of them are short-lived and the only really practicable method of renewal is by raising seedlings. The Iceland Poppy, *Papaver nudicaule*, is a case in point. Like the Foxglove it should be treated strictly as a biennial. The extraordinarily large flowers sometimes seen in florist's shops represent a very fine strain combined with the best of cultivation. The seeds are sown, as soon as ripe, in really good, deeply cultivated soil and the seedlings transplanted, as soon as large enough to handle readily, into their permanent quarters, leaving 15 ins. between the plants. A few of the very best plants are marked for seed and the expanding blossoms gathered each morning for market from the rest. By this means the strain is kept up to the mark or even improved. *Papaver alpinum*, the Alpine Poppy, is little more than a miniature of the last-named species, but, oddly

enough, it is far more perennial. There is a great variety of colouring with this charming little species and a fringed strain with deeply cut petals is now obtainable, which, if kept apart, reproduces itself fairly true from seed.

It is exceedingly interesting to raise good forms of the Oriental Poppy from seed. Seeds from one of the spreading-habited, salmon-pink forms will often produce a proportion of erect growing plants with crimson-scarlet flowers and an immense variety of other forms besides. Do not try to rush them into commerce, however, as magnificent named varieties; for the sorts sent out by Mr. Amos Perry represent the pick of many thousands of seedlings, and those not raised indiscriminately but from carefully selected crosses. Do not be tempted to introduce *Papaver pilosum* into the garden, either in the form of seeds or plants. It has no special beauty and once established is almost impossible to eradicate. It seems to cross readily with *P. orientale*, too, and the resultant seedlings are also worthless.

Florists' Pentstemons are exceedingly interesting to raise from seed. A start should be made with

a selection of really first-rate named varieties and inferior sorts should be ruthlessly discarded, nor should fine blossom and well proportioned spike be allowed to outweigh a bad constitution and a tendency to "rust." From a sowing under glass early in January many plants should flower the same autumn. It is better, however, to sow the seeds as soon as ripe and winter the young plants under glass. Some day, perhaps, an amateur will raise a pure white florists' Pentstemon. There is no such thing at present! There is room, too, for improvement in the pale shades generally. There is an immense number of Pentstemon species, probably all easily raised from seeds. Some of these are every year offered by nurserymen who specialise in seeds of hardy perennials.

The perennial Sea Lavenders, *Statice*, again, are readily raised from seeds. The most generally useful plant is *S. latifolia* but, unfortunately, this is quite the most difficult to increase satisfactorily from seeds. A very variable plant, undoubtedly the forms with deep coloured, almost violet flowers are most desirable, but however carefully one may select one's seed parent,

a proportion of plants which will give wash-coloured flowers is produced. Still, seed raising produces a number of good plants quickly and after selection has been made, vegetative propagation will quickly still further increase the number. *SS. Gueldri, eximea* and *tartarica* are other worthy species to raise from seeds.

Perhaps it may be as well now to deal with a few rock plants of easy culture from seeds, leaving to a subsequent article consideration of what are usually considered more difficult species. The generality of Alpine *Violas* are as easy to raise as florists' *Violas* or *Pansies*, which presumably most amateurs have at one time or

WHITE FOXGLOVES. ESPECIALLY ADMIRABLE IN WOODLAND.

another raised from seed. Such are the rosy-purple *V. bosniaca*, the glorious Grecian Violet, *V. gracilis* with flowers of imperial purple, *V. calcarata*, extraordinarily variable and, sometimes, wondrously ugly and, if wanted, *V. cornuta*. This last, however, can be increased at express speed from cuttings and as the seedlings are usually unsatisfactory in colour, few will wish to bother with it. *V. lutea* of our Derbyshire and Yorkshire hills is also readily raised from seeds, but likes mortar rubble in the compost. A word of warning! No *Viola* species in the rock garden is safe from cross-fertilisation. Imported seeds only should be sown.

The alpine *Campanulas* for the most part seed freely and the seedlings are easy to raise in pans of gritty soil with a proportion of old mortar rubble. Many of the seeds are fine so that careful watering is necessary and if any artificial heat is given a sharp look-out must be kept for green fly. Suitable species are *CC. carpatica*, *c. turbinata*, *pulla*, *barbata*, *sarmatica*, *Portenschlagiana*, *garganica* and *Raddeana*. The nearly related *Edraianthus* (*Wahlenbergia*) *serpyllifolius* likes similar conditions. Of taller *Bellflowers* suitable for the border which are worth raising from seeds, mention should be made of *CC. persicifolia*, *lactiflora*, *latifolia*, *bononiensis* and *alliarifolia*. The first named is an invaluable border plant which varies greatly from seed. Fortunately almost every form is beautiful. *Campanula lactiflora* is fine for massing and the best coloured forms breed true from seed it paler ones are not tolerated in the neighbourhood. *C. bononiensis* is a particularly slender and graceful species for use towards the front of the border where its spiry habit serves to break monotony of outline. *C. alliarifolia* is an admirable species for wild garden or woodland.

The *Cranesbills*, if we may thus group together the very nearly related *Geraniums* and *Erodiums*, are quite readily raised from seeds and many of them if planted in a favourable situation will proceed comfortably to naturalise themselves. Unlike their cousins the *Pelargoniums*, almost all species are entirely hardy. There is, by the way, one species of *Pelargonium* which is hardy enough and very beautiful and interesting withal. This is *P. Endlicherianum*, with brilliant rose flowers. It is readily raised from seeds. Some of the *Geraniums* may be increased with extraordinary rapidity by division—such an one as *Endressii*, for instance. It is well to raise from seed those of slower growth and more compact habit, such as *Traversii*—most beautiful of all, with its silk-covered foliage, but alas! not over-hardy—*cinereum* and *argenteum*, two close-growing species for the rock garden and the beautiful blue *Wallichianum*. The Bloody *Cranesbill*, *Geranium sanguineum*, a handsome native plant, is also worth raising from seed. All the *Erodiums* are best raised from seed. The largest species is *E. Manescavi*, with brilliant purplish red flowers, and the choicest and neatest *E. ananum*, with soft rose blossoms, but there are a number of others, all interesting.

Many *Silenes* are of the easiest culture from seed. The writer considers *S. alpestris* the best species of all, with its beautifully fringed flowers, startling in their purity of whiteness. This is an exceedingly accommodating plant and naturalises itself from self-sown seeds as well as increasing rapidly by underground runners. *S. Schatta* is exceedingly valuable as an autumn-blooming species, with vivid purplish-rose flowers in dark calyces. It is readily raised from seed, but, strangely enough, seldom increases itself by self-sown seedlings. *S. vallesia*, about which there was recently (page 608) an interesting note in *THE GARDEN*, is also easily raised from seeds. *S. Saxifraga* is another alpine species easy to raise.

THE GRECIAN VIOLET, VIOLA GRACILIS.

SINGLE ROSES

A FEW weeks ago *THE GARDEN* gave a good deal of notice to the single Rose—species and otherwise. I do not remember to have seen it pointed out, however, that the cultivation of most of these Roses is possible under conditions which would render the raising of doubles or bedding varieties a disappointing occupation. That, I think, is a very strong argument on behalf of furthering the popularity of the wild or other single Rose, for it means that a vast number of people who could never hope to become rosarians in the orthodox sense, owing to soil conditions or locality, might enjoy the growing of hundreds of Roses whose charms are every bit as fascinating (some think a good deal more so) as those of our Hugh Dicksons, Chateaux and Testouts. To take our own case, we once tried a good many of these double, or decorative, sorts, and none of them ever proved that "the game was worth the candle." They are miserable in our hot, shaly, unretentive soil. So, having struggled through the novice stage, in which one is so apt to try to achieve the impossible instead of concentrating upon plants for which the soil is really fitted, practically all the double Roses were scrapped and singles introduced. From that day we have enjoyed abundant success, for the conditions which the bedding Roses rejected happened to be just what the others liked.

If the National Rose Society does not cater for our single Roses at its shows, which I am assured is the fact, it matters little. I very nearly wrote "so much the better!" Not that I have any animosity against the N.R.S. in particular, but a long experience of shows and shewing impresses upon me the belief that the "fancy" exhibit, whether it is a Smithfield ox, an Olympian Orpington or a prize Pansy, is a vain thing; but that is by the way. What I mean to say is that it matters little what the attitude of organised Rose culture happens to be towards the single Rose, because the latter already has hosts of admirers, and they are increasing year by year. The wish may be father to the thought, but I believe that the star of the single Rose, and especially the species, is rising, and that we are not far from witnessing in this country a cult of this class of Rose which I read is already firmly established in America.

The introduction of the Penzance Briars, with their wonderful range of choice colours and ease of culture, doubtless gave a great impetus to the popularising of the single Rose. Whether these Penzance Roses are glowing with the wonderful tints of *R. lutea* on the one side or reminding us of the incomparable rose pink of our own wild Briar on the other, they are always irresistibly attractive. Many of them have fragrant foliage, and they produce an autumn-winter crop of gaily coloured fruits. Pruning they are better without, and the majority of them will make large, sturdy bushes which will hold themselves up without support. If the individual blossom is soon over, the long, arching branches fully compensate for this by producing an almost interminable succession of bloom during the pleasantest part of the gardener's year, and not a few varieties will often again break into partial flowering in autumn. These Roses, as I have suggested, will flourish where the average bedding variety would do no good. In our gritty, sharply drained soil, for example, they are simply given a little old manure and semi-decayed vegetable compost under and around the roots at planting-time and left alone.

The mention of *R. lutea*, or the Austrian Briar, reminds me that in this species we have a single

Rose of large size, perfect form and most magnificent colouring, one that is an ideal plant for warm banks on any light soil. There are two well known forms of this superb species called the Austrian Copper and the Austrian Yellow. The latter is a good rich yellow, the former a fiery blend of orange, copper and scarlet with a reverse of real old gold. *R. lutea* makes a loose-habited, elegant bush of medium height, and the flowers are borne in profusion on the gracefully arched and pendulous branches.

Quite the most lovely single Rose of recent introduction is *R. Moyesii*, of which there has been so much written of late that one hesitates to add to the eulogy of this enchanting thing. *R. Moyesii* has so many good features that it is difficult to say which is the most charming. There is the peculiarly thick and velvety texture of the petals and their fascinating colour—a very deep blood crimson with rich ruby lights is as near as

THE RAMANAS ROSE, *ROSA RUGOSA*.

I can get it—and this centred by a conspicuous mass of almost saffron yellow stamens whose anthers shed their contents in a scintillating dust of gold upon the crimson velvet beneath them. Yet another very characteristic feature of this handsome Rose is the durable nature of the blossoms, which remain untarnished for several days, perhaps a week or even more. The curious tilt of the flower, which is slightly inverted, as it looking downwards, has doubtless no little influence in prolonging its life and making preparations for the enormous bottle-shaped fruits which follow.

Then we have *R. Hugonis*, another Chinese introduction, and one that was raised at Kew from seed sent over by Father Hugh Scanlan, after whom it was named. This lovely species, whose foliage and prickly stems suggest the Scotch Rose, is also admirable for any light, even poor, soil. It is usually a very vigorous grower, throwing up 6ft. to 8ft. canes, which branch freely and sweep over in ropes of bright yellow blossoms.

All who have ever enjoyed the delicious fragrance which blows across sandy heaths and seaside links, where the creamy yellow Burnet Rose grows so profusely, will have experienced one of the

most delightful features of the Scotch Rose (*R. spinosissima*), which is an off-set of the wild Burnet. There is now a long list of Scotch Roses, all of which make first-rate plants for dry, hot banks, while the colours, if one includes the doubles, range from a good deep rose to blush, and from yellow to white. Perhaps the best of the singles is *R. altaica* (*spinosissima maxima*), whose abundant white flowers (May) are about 3ins. across, but there are various forms, all of them dwarf and useful for grouping where most other Roses would fail to exist. The fruits are almost black and the size of Sloes.

Another species which does remarkably well here in the meagre soil of a woodland slope is *R. alpina*, at once distinguished by its thornless stems and sea green, or emerald, foliage. This is also an early bloomer, the bright rosy red single flowers opening in May. These are followed by long and narrow, orange-crimson fruits. In some soils this Rose appears to grow to a considerable height, but it remains a medium-sized bush where the land is none too good and probably

flowers the more abundantly. The dwarf *R. pyrenaica*, with thorny stems, is a form of the above.

R. nitida is an excellent little species of about 18ins., the blossoms (summer) being a good bold pink. The stems of this Rose are thickly covered with crimson spines, of which the colour is brightest during winter, and the fine glossy leaves, which are entirely deciduous here, assume rich autumn tints before they fall. *R. indica*, another dwarf, said to be the original China Rose, is a parent of many of our bedding and Monthly Roses, and one that possesses some of the most valued attributes of these latter. The colours in some of the best singles, for example (notably Miss Lowe), are remarkable for their purity and depth, and *R. indica* is, perhaps, the most perpetual bloomer among the singles we possess.

When many of these Roses are going out of flower (July or later) *R. lucida* opens its lovely fresh pink blossoms. These are borne profusely on established plants; they open flat, are over 3ins. across, and could hardly have a more effective setting than that provided by the copious and very glossy foliage. The flowering season may extend until autumn is approaching, when the

fruits become a bright red and the falling leaves develop generous shades of yellow and bronzy purple. This is quite an easy doer in any average soil, even in the woodland where its red-brown branches have a pleasing effect during winter. *R. hinda* makes a large bush, spreading by underground suckers. There are several varieties. For a warm, sunny spot *R. berberifolia* Hardii,

its yellow cistus-like flowers being blotched with crimson, can be recommended, but it is not in our experience a "good doer," as most of the others here mentioned are. It is, however, well worth a trial. "Hebe's Lip," said to be a form of *R. b. Hardii*, and bearing white flowers with a pectee edge in carmine, is tolerably easy tempered. *R. sericea* is one of the most distinct and desirable

of all wild Roses, its four-petalled flowers being arranged in the form of a Maltese cross. The very dark green foliage and red spines are also distinctly uncommon features. It is another of the May bloomers, and related to the curious *R. pteracantha* with its strange armature of spines
North Wales. A. T. J.

(To be continued.)

ZENOBIAS AND ALLIED GENERA

THE many ericaceous plants still commonly known to gardeners as species of *Andromeda* are now divided by botanists into no fewer than nine genera. These are known respectively as *Andromeda*, *Pieris*, *Lyonia*, *Leucothoe*, *Cassine*, *Cassiope*, *Zenobia* and *Enkianthus*.

Of these genera *Pieris* and *Zenobia* stand out "head and shoulders" above the rest as valuable garden plants. *Zenobia speciosa* is a hardy deciduous or sub-evergreen shrub with a rather thin habit of growth. The flowers, which are pure white, are produced in June and July on the terminals of the previous year's growth. The accompanying illustration will give an idea of their arrangement and beauty.

The variety *pulverulenta*, also illustrated, is very distinct and by some botanists considered a distinct species (*Z. pulverulenta*). It is really even more beautiful than the typical plant. The

picture shows some essential differences between the two plants, but *pulverulenta* is readily distinguished in the garden by its very glaucous foliage. The young shoots are also glaucous. Neither of these two interesting and beautiful shrubs is grown nearly as much as it should be. Both kinds may be raised from seed, but propagation under glass from cuttings of half-ripened wood is not difficult.

The genus *Pieris* is better known in gardens, *P. floribunda* being a fairly common, very hardy and exceedingly early-flowering species. The glossy ovate evergreen leaves are about 3ms. long, and the hanging pitcher-shaped flowers are borne in erect terminal panicles each consisting of several slender racemes. This is a slow-growing shrub, but it ultimately attains a height of 6ft. or so. At its best in March or April, it is not uncommon for some of the blossoms to expand in mid-winter. Gardeners often call it the Lily of the Valley shrub,

Pieris japonica is a larger and more rapid grower, which attains in favourable situations a height of about 10ft. It is, however, not nearly so hardy as *P. floribunda*, and the graceful pendent racemes are very liable to be damaged by frost. The western edge of woodland is a good place for it or a western exposure in the rhododendron dell should suit. This is a particularly beautiful shrub where it succeeds, being less formal in outline and more graceful in flower than *P. floribunda*. *Pieris formosa* is even more handsome than *P. japonica*. It makes a larger shrub, has finer foliage and much larger and handsomer flower panicles. Unfortunately, it is only really at home near the sea coast, though it grows outdoors at Kew. *Pieris taiwanensis*, which this year received an award of merit from the R.H.S., is closely related. This was illustrated in *THE GARDEN*, page 142. Soil which suits *Rhododendrons* will grow all the plants mentioned.

A SPRAY OF ZENOBIAS SPECIOSA VERA.

THE VERY DISTINCT SUB-SPECIES Z. S. PULVERULENTA.

AN

ILLUSTRATED WEEKLY JOURNAL

OF

Horticulture in all its Branches.

Founded by W. Robinson in 1871.

EDITED BY R. V. GIFFARD WOOLLEY.

VOLUME LXXXVI.—1922

LONDON.

Office: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.

Published by "COUNTRY LIFE," Ltd., 20, Tavistock Street, Covent Garden, W.C., and by
GEORGE NEWNES, Ltd., 8-11, Southampton Street, Strand.

THIS (THE EIGHTY-SIXTH) VOLUME OF "THE GARDEN"

IS DEDICATED, BY PERMISSION, TO

LEONARD G. SUTTON

MR. LEONARD SUTTON, the present senior partner in the great Reading seed firm, is the youngest son of the late Mr. Martin Hope Sutton. Born in 1863, and thus in his sixtieth year, he was educated at Wellington College and the Royal Agricultural College, Cirencester. On his return from Cirencester to take up business with the firm of Sutton and Sons, which he entered in 1884, Mr. Sutton interested himself in agricultural work in connexion with Grasses and Clovers. In 1901 he was a member of the Departmental Committee appointed by the Government to report on the conditions under which agricultural seeds were then sold. "Mr. Leonard" ultimately relinquished this side of the agricultural business to his nephew, Mr. Martin H. F. Sutton, the son of his eldest brother.

As a young man Mr. Sutton resided for some time in the seed-growing districts of Germany. On his return he devoted himself enthusiastically to the culture of flowers from seed. If one of Messrs. Sutton's catalogues of date prior to 1883 is compared with that of the present year, it shews the marvellous technical developments that have been made in the illustration of flowers, whether from drawings or photographs.

In 1890 Mr. Sutton paid a long visit to the United States and Canada, and stayed in the seed-growing districts of California, where seed-growing was then in its infancy. The predictions he then made as to the development of the industry have been abundantly fulfilled.

Mr. Sutton has been closely identified with the development of the Agricultural and Horticultural Departments of University College, Reading, and has for many years been on the Council of the institution. In 1910 he helped to organise a deputation—consisting of himself, the Principal, the Director of the Agricultural Department and the Professor of Botany, Professor (now Sir Frederick) Keeble—to those Universities of Canada and the United States of America in which horticulture and agriculture formed an important part of the curriculum. It is largely due to the knowledge acquired there and the consequent report on the subject that such important developments have taken place in our own higher education in this important branch of science.

Mr. Sutton has been a member of the Corporation of Reading for many years, and was Mayor for two successive years during the war. His labours during those sad and trying times, for Red Cross, for the War Pensions Committee and in other directions, will always endear him to the townfolk of Reading. He is at the present time Chairman of the Reading Education Committee and of the Berkshire Territorial Army Association. He is also a representative of the diocese of Oxford on the National Assembly of the Church of England.

It will be seen, therefore, that Mr. Sutton's activities are by no means confined to the great business of which he is senior partner. To be the head of a business so well known, admirably organised and highly respected as that of Sutton and Sons is in itself a distinction of the first rank. "Suttons" is, rightly considered, more than a business—it is an institution. It is known and respected throughout the English-speaking world and in all foreign countries of any importance. Its best testimonial is its world-wide trade!

EUROPEAN MARTAGON LILIES

WHEN I was a boy, I found once, on the slopes of the Jura, some disagreeable-smelling dark flowers, banging from a long spike and giving altogether a candelabra-like effect which astonished me. My schoolmaster said it was the Martagon Lily, but I could hardly believe that a Lily—I only knew the Madonna Lily, which my father had in his garden—could have such an appearance—and such an odour. The master, none the less, was right and I was wrong.

Later on, I found in my mountain rambles several other Lilies, all belonging to the same type as the Martagon. Of these, some of them being treasures, I will write a little for the benefit of readers of my dear old GARDEN.

First, I will recount a curious coincidence, proving the possibility of auto-suggestion to an enthusiastic botanist. I was once saying to one of my sons that I had never in my life found the white form of the Martagon Lily and that I would immensely like to find it once. This I said when I was climbing on a green slope near Bourg-St.-Pierre in the Valais just below our alpine garden "The Linnæa." Some two or three minutes afterwards only, we found three superb plants of it, the flowers showing above the herbage! I have never found it since that occasion—it was in 1890. The white form is very rare in Switzerland and is often considered as a garden variety. Of course, it was not so luxuriant as those of which you have published photographs (pages 494 and 572), grown in an Irish garden and at Kendal by the Hon. Mrs. Cropper. I know that there are, in English gardens, other clumps which are equally fine. I could never get them, however, and I fear I shall die before possessing the pure white form. The late Leichtlin introduced some forty years ago from the Montenegro mountains a form of Martagon with dark brown and shining flowers, which is called *dalmaticum* by Visiani and which is seldom seen in gardens now.

At the end of June, 1904, I had the brilliant sight of an immense field of *Lilium carnolicum*, the beautiful red Martagon of the South Austrian Alps. I was climbing the Monte Simmauo (where war has since brought distress and ruin), and after having traversed fields of sky blue *Lithospermum graminifolium* mixed with *Linum viscosum* and *Serapias longipetala*, I came to the top, where an ideal view shewed us to be near the boundary of Austria and the gold-coloured Dolomites. Then, suddenly, we came upon a pasture as red as the fields of Poppies in England. What is it? said I to my guide. He did not know, but when we came to it it proved to be a field of *Lilium carnolicum*. It grows in a rich meadow with a north aspect, the soil being deep in humus.

Last year, at the end of May and beginning of June, I was rambling in the Maritime Alps and found, between the stones of the Var Valley, nice patches of *Lilium pomponium*, that marvellous red Martagon which is the brightest coloured of all Lilies, brilliant as are *Lilium chalcedonicum* and *L. tenuifolium*. I had never before seen *Lilium pomponium* in its wild state. I had got

it, of course, and cultivated it fairly well, but the sight of these masses of crimson spikes adorning the dark, stony and barren slopes and overhanging the railroad seemed to me to be a picture of the greatest beauty. The graceful, slender stalk

A SPIKE OF *LILIAM MARTAGON DALMATICUM*.

(30 to 50 centimetres high) bears three to five Martagon flowers of the deepest vermilion—almost as deep as *L. chalcedonicum*, which it so greatly resembles—glowing under the powerful and hot sunlight of the Maritime Alps. To my great surprise, the bulbs were sunk in rocky crevices or among broken stones, and very hard to get. We could get nothing but the young ones, as the oldest were too deep in the rocks, seldom in any soil—and how difficult the flowers are to dry for the herbarium!

I returned last summer in the month of July, hoping that I could take some of these bulbs from the ground when at rest. But alas! it is impracticable in such stony ground to go deep enough to secure them. They are impossible to reach. Later on, however, in the Tinée Valley, and also in the Roya Valley, I came upon them in grassy slopes, where it is easier to collect them. In that

habitat, always on very steep slopes in half shade, they grow in light soil, but they are very deep there too. Sometimes the understalk is horizontal, like a stolon: in this case it makes from three to six little bulbs one after another along the stalk, and each of these bulbs gives a little plant. It is not quite the same method of increase that we find with some North American Lilies (see in Dr. Wallace's "Notes of Lilies," pages 110-111), for they are, I think, bulbils of the same nature as those we find on *Lilium bulbiferum* and *L. tigrinum*; only that the bulbils, instead of being along the stalk are, in this case, in the soil and only on the under part of the stalk.

Lilium pomponium is the glory of the vegetation of the Maritime Alps. It seems to me to be not so rare as is commonly supposed, and I know more than twelve stations in the country. Above Mentone it covers some extensive meadows, and in the Vallon de Cairns a friend of mine found fields of it. It is, of course, the Western form of *Lilium carnolicum* and the famous and still more violently coloured *Lilium chalcedonicum* is the Eastern form of both. The first goes from North Italy to Macedonia on the Monte Orbeli, and *chalcedonicum* is the Grecian species. There is an intermediate one called *Lilium Heldreichii* by Freyn, which grows in the Attic Mountains.

At last Chelsea Show Messrs. Wallace exhibited a lot of *Lilium tenuifolium* from Siberia, which was one of the most brilliant things in a fine collection. It is a dwarf plant—I think the dwarfest of all Lilies—and has very narrow leaves; the flowers are of the deepest imaginable crimson. I grew it forty years ago, but lost it more than twenty years ago, as it is difficult to keep here. The three others are easier here, and, some fifteen years ago, *Lilium chalcedonicum* adorned numerous gardens in our Jura country. Now it is very seldom seen.

In the Pyrenées *Lilium Martagon* is common, but here and there, especially on the Spanish side, one may find, in very shady places, the Yellow Martagon, *Lilium pyrenaicum*. It is distinguished from the Common Martagon by its leaves being distributed along the stalk—not in whorls as they are in the Common Martagon—and by its yellow flowers with red anthers. The plant has been sent out in such quantities by the plant merchants there that it is now rare in the High Pyrenées district. You can see it in some inaccessible rock walls, near Bagnères-de-Bigorre, always facing north, and in certain damp woods. Its culture is very easy; it likes just such a shady corner in the garden as does the Martagon.

Florence, Geneva.

HENRY CORREVOY.

SPRAY FLUIDS AND SPRAYING

Spray early, spray thoroughly, but spray with forethought and judgment.

THERE are many ways in which spraying may be rendered ineffective and useless, and there are circumstances that may render spraying unnecessary and therefore extravagant, the whole pith of the subject being that spraying is not a matter of conforming to charts, programmes and cut and dried rules, but must be made a matter of careful study and practical judgment.

During the early part of the dormant winter period the spraying with caustic wash of old trees that are choked with lichens and algae is an urgent necessity, but that does not mean that because it is December or January we should spray healthy,

clean young trees with caustic soda, nor even that it must be annually used on old trees. It is probable that when a tree has become badly smothered with moss or slime, one season's spraying will be insufficient thoroughly to cleanse the whole of its trunk and limbs, and a second year's spraying is then necessary. When, however, the tree is cleaned, caustic soda has fulfilled its mission, and its use on clean trees is superfluous. It is erroneous to suppose that the soda kills the eggs of insect pests. What it does do is to burn away the moss and slime that afford harbour in which the eggs may pass the winter. There are few, if any, sprays which may be safely used on living trees that will kill the eggs of destructive insects. To combat the insect pests we must either use sprays that will kill by contact or that will make the feeding ground of the pests so obnoxious that the pests are held at bay. Therefore most insecticides are for spring, summer or autumn use, the last named being used with the object of preventing female moths and flies from laying their eggs where they would be detrimental.

Caustic soda is by no means either pleasant or easy to use. Both the dry powder and the fluid will burn the skin if allowed to come in direct contact with it, and the operator should have his face thickly smeared with vaseline, and should wear leather gloves. Old clothes or overalls are an absolute necessity, and one should take care to work with one's back to the wind, but, of course, a very windy day should not, in any case, be chosen for spraying.

Burgundy mixture, which is a combination of copper sulphate and soda, is effective as a fungicide as well as an eradicator of lichen and algae, and either this or the familiar and well tried Bordeaux mixture should be used during the leafless period, where such fungoid pests as apple or pear scab, brown rot, and even canker have taken a hold. For such pests it is highly probable that spraying will be necessary for two or even three successive seasons, but the obvious deciding factor should be whether the trees and their crops the season after spraying are completely or only partially freed from the pest. The task of dealing with aphides is not only a summer operation, but an all the year round task. Millions of eggs nestle in the cracks and chinks of trees, bushes and plants, and if by burning away their protective lichen, etc., we can shitt the eggs, that is an accomplishment worth the effort.

In January, or at the latest February, lime-sulphur may be used, and relied upon materially to reduce the number of aphides that hatch out. Exactly what the action of lime-sulphur is may be a matter of conjecture rather than certainty, but it is very probable that by sealing over the eggs, necessary air is excluded, or that the air which does enter the egg is impregnated with sulphurous vapour that renders the life-germ within too weak to hatch out. A great deal of confusion of ideas exists in regard to lime-sulphur spray, probably due to the frequency with which sulphur is recommended as an antidote to mildew on Roses, Vines, etc. I have heard a traveller for a firm of horticultural sundries-men announce with ready confidence that lime-sulphur will do as much as any spray toward ridding trees of fungoid diseases. Used in spring it may be and undoubtedly is very effective in this direction, but I have not seen anything to justify placing lime-sulphur in the place of Bordeaux mixture for winter use. It has not the power of the latter, but for that very reason it may be used during the leafy period when Bordeaux would ruin the foliage. One great advantage about using lime sulphur as a deterrent to the hatching of aphides quite early in the New Year is that when trees are thus treated birds do not damage the fruit buds. That is a phase of spraying which is not

frequently dealt with, but it means a great deal to the owners of fruit trees, especially in districts surrounded by woods and fields. With these two main facts regarding lime-sulphur in view—firstly its efficacy against aphides, and secondly its preservation of fruit buds from damage by birds—there would seem to be a very good ground for advocating that this spray should be used regularly and liberally, even to the extent of spraying healthy as well as unhealthy trees and also bush fruits; but, to get the full benefits, the application should be quite early in the New Year, not held over until mid-spring as is so frequently advised. We have quite other objects in view and other pests and

diseases to combat at that season of the year. So far as lime-sulphur is concerned it may be applied to small trees and bushes by means of a small hand sprayer or a good fine-nozzled syringe, but caustic washes call into requisition well constructed spraying machines fitted with long lances, enabling the operator to stand a good distance from the jet. Look well to the spraying machines, and see that pumps, washers and nozzles are all in good order. Never put the sprayer away after using caustic wash without thoroughly cleansing the machine. Carelessness in this detail may soon cause the wastage of shillings or pounds in repairs.

A. J. MACSELF.

SOME SHRUBS OF A WINTER GARDEN

THOUGH my enthusiasm for the winter garden is not warm, being largely measured by the degrees of the thermometer, one is grateful to those rare occasions which afford a ray of bright colour, a whiff of fragrance or some brave promise vouchsafed by a breaking bud.

It is, after all, rather a survival of autumn than a note of winter that induces me to open this subject. Seen in the low sun of a December day, what is finer than a good specimen of *Berberis vulgaris*? With its pendent bunches of fruit fired to a dazzling scarlet by a touch of frost, this fine old Barberry is a spectacle to be remembered. About 8ft high and nearly as much through, the gracefully hung branches are laden with their brilliant crop, a crop that is usually untouched by birds, save in times of great severity, and one that retains its splendour of colouring from the time the last golden leaves are shed until signs of the lengthening day are unmistakable in the western sky. We cannot afford to overlook the

merits of this none too familiar old shrub, for they are unique. Here, at any rate, it is a winter-fruited species without rival, and the type is still, I think, superior to its varieties.

Among the earlier *Daphnes*, *D. Mezereum* is a splendid thing where it does well, its rich purple or the ivory white of the variety *alba* being unspoiled by the worst the weather can do; but although the cottagers hard-by can grow this species to perfection in the old soil of their little plots, there is something about our woodland loam that it does not like, repeated plantings languishing without an effort. However, there is some consolation in the fact that we can satisfy *D. Bлагayana*, and as I write (December 12) its big buds are bulging with promise. *Daphne pontica* is one of the good old things, and its lily-like fragrance, so generously disseminated in the garden air of the early year, is alone enough to claim for it a place. Though much like *D. Laureola* (*Spurge Laurel*), the tubular flowers of *pontica* are a better yellow, their perfume can

LONG AND ELEGANT BRONZY LEAVES AND CRIMSON FRUITS OF COTONEASTER SALICIFOLIA

easily rival that of *D. Blagayana*, or the much later *D. Cneorum*, and the shrub is one that will do in a shady place or under the drip of trees. *D. pontica* usually flowers after the Spurge Laurel, but it is often in full bloom by mid-February. To-day the peculiar green of its foliage is very attractive against the prevailing brown of the woodland floor.

Berberis Aquifolium (*Mahonia*) can always be relied upon to give colour when the first Snowdrops are appearing and the buds are already breaking; but not many forms of this species make me very enthusiastic. Their flowers are welcome enough in mid-winter, but they are produced in a bunchy manner, the clusters seem to lack form and appear at a time when the foliage is apt to look shabby and mean. Of *B. nepalensis* I cannot speak from experience, for the specimen we have has not yet overlooked the root disturbance to which it was subjected three years ago, an interference to which all members of this clan seem peculiarly sensitive. *B. Bealei*, however, made an exceptionally good-tempered recovery after planting, and is now a fine bush some 4ft. or more in height, growing vigorously and flowering regularly every January. This species is copiously furnished with very large, horny leaves of a pleasing shade of green, and the many blossoms, bright yellow and scented like Lily of the Valley, are arranged in a bold and elegant cockade at the tip of every leading branch. Though somewhat susceptible to severe frost in the bud stage, these blossoms appear to be perfectly hardy, and are followed by plum-coloured fruits which are soon discovered by the blackbirds.

Beneath deciduous trees, thinly disposed, our *Rhododendrons* usually escape their worst enemy—white frost—and also derive considerable shelter from wind. Among them *R. nobleanum* in rose-crimson is one of the first to flower, but it does not often precede the excellent *R. præcox*, of which a dozen plants or so form an irregular group on the woodland bank. The delicately tinted flowers of this charming hybrid are extraordinarily hardy, and the rich, glossy, myrtle-green foliage singularly attractive. *R. Silberhad*, which I first saw one early February day in Mr. E. C. Buxton's beautiful garden, where it grows to perfection, is also one of the forerunners of its race, its buds beginning to swell soon after Christmas. The medium-sized trusses of this splendid variety are produced with great liberality, the pretty, crimped blossoms being a lovely silver pink, and the bushes are in bloom for many weeks. This season *R. Silberhad* has been rather marred by being thrown out of its reckoning early in the autumn of last year, when many flowers opened in response to the rain which followed that baking summer. The bushes now, however, have sufficiently settled down to promise a fair shew of colour presently, closely to be followed by the superb crimson-scarlet *R. Jacksoni*, which is still one of the most charming and reliable of the early ones, the buds often shewing their ruby tips in February here (North Wales).

Most of the conifers, great and small, are seen to fullest advantage in winter, and that not only because they now have the field so much more to themselves. I can do no more here, however,

than refer to one little grouping which occupies an elevated position on grass above some rock walls. It consists only of three shrubs, *Juniperus prostrata* spreading over a lichened boulder, by which stands the dwarf and golden form of the Scots Pine, while, a little detached from these is a small upright specimen of the common *Juniper* of the Scottish hills. The rich green, the gold and the blue-grey of this trio are never quite so good as they are at this season, and the informality

hedgerow and hillside in the locality, other berrying plants should carry their crop unusually far.

Viburnum rhytidophyllum is yet another shrub that will not escape attention in a winter garden, its large, deeply veined, velvety leafage being exceedingly handsome and weather-proof. Though often despised because it has been overdone and is so frequently ill-treated, the Common Portugal Laurel (*Prunus lusitanica*) is a goodly thing

MOST WELCOME IN WINTER DAYS, THE MEZEREON, *DAPHNE MEZEREUM*.

of the group gives some character to a portion of a turfed terrace of very poor soil which might otherwise have appeared flat and uninteresting. As good fortune would have it, some plants of *Gentiana acaulis*, which happen to be by the little Scots Pine, have now several flowers fully expanded, the deep blue and the gold being a particularly telling contrast—as witness the Gorse and wild Hyacinths on the hillsides in May.

It is in winter that one can perhaps most fully appreciate the glossy, bronzy green and ruddy stems of *Cotoneaster rugosa* var. *Henryana* and *C. salicifolia*, their long and elegant bronzy leaves seeming too delicate for so rough a world, are the more valued in consequence; but of the winter-fruited *Cotoneasters* none can equal the evergreen *C. pannosa*. The grey-green, downy foliage, ruddy stems and long, gracefully arched, whip-like branches of this fine species are admirable at all seasons. It is, however, from late autumn throughout the winter when those branches are copiously hung with clusters of brilliant crimson truss, that *C. pannosa* excels as one of the handsomest species of its attractive race. Only in the severest weather do birds touch the berries in this garden, and that much may also be said of those of *C. Francheti*, also an evergreen with a foliage much like that of the foregoing; but having compared many specimens of these two shrubs, there is no question as to which is the more beautiful, *C. Francheti* appearing angular and coarse beside the refinement and elegance of *C. pannosa*. As there is such an extraordinary abundance of Holly berries this season on every

to look upon at this season, affording a shade of deep green which is uncommon and which seems to blend peculiarly well with the purple stems. Left to grow naturally the Portugal Laurel is of no mean worth as a flowering tree. The most cheerful of the Broom family to-day is the hardy *Genista monspessulana*, which might easily be mistaken for *Cytisus racemosus* (*Genista fragrans*). *G. monspessulana* (sometimes listed as *G. candelans*) is almost an all the year round blossomer, and even during the short winter period when there will be no more than a sprinkling of blossoms, it takes advantage of every mild interlude, putting out fresh shoots and regarnishing its soft, delightful green in readiness for the flood of yellow with which it will be covered in spring. The afore-mentioned *G. fragrans*, planted out on a warm shaly bank some two or three years ago, has thus far proved hardy enough to withstand considerable frost. The trouble with this pretty thing, however, is that it mistakes a few mild winter days for the coming of spring and immediately hastens to put forth its delicate racemes of flower-buds, which are consequently liable to be nipped. Still, the vitality and optimism of this plant are so abounding that it takes little heed of these temporary checks.

The Caucasian form of *G. tinctoria*, which grows to about 4ft., is another member of this race which is apt to misunderstand our climate. We have, for example, a specimen of this Broom now bearing a number of fine heads of bloom, which, with average weather, will be in flower at Christmas and after.

J. W.

NOTES ON TRAPPING VERMIN

A few hints on simple and inexpensive means of destroying pests which injure and devour crops.

NO garden is free from the unwelcome attention of such pests as rats, mice, moles and voles, and there are often enquiries in the gardening press for information as to their destruction. There is nothing surprising in this when one considers the knowledge and skill required to capture the more cunning of them. The successful trapper must be a keen observer of the habits of wild nature, and must possess an intimate knowledge of their ways. A few hints on simple and certain methods may be welcome to many who have suffered loss and damage by their ravages. To most amateurs the capture of the mole presents the greatest difficulty, and without skilled help or advice it is certainly difficult to trap it in the loose soil of a garden. The common iron trap is generally used, and preference should be given to one made of wrought-iron. The cast-iron variety is too clumsy. The mole usually has its retreat in a dry hedge-bank, shrubbery or among the roots of large trees, and between these places and its workings or feeding ground the main run must be sought for. For this nothing is better than a small pointed iron rod with a good handle—an enlarged iron skewer, in fact. By pushing this into the ground at very short intervals the run will be found by the point dropping in easily. If the run is under a grass path and is an old one, a slight depression will be seen above it. The main runs are used for years and, once found, should be remembered. A neat hole should be dug with a trowel just large enough to take the trap. It must be fitted centrally so that the mole does not come in contact with the trap until it reaches the trigger. Place two thin pieces of closely cropped turf, grass side downwards, on the jaws of the trap and cover all with grass or leaves to exclude light.

Another good trap, not generally known, is the pitfall. It may be used in the main runs with great advantage, and is about the only one of much use in soft earth. Deep earthenware pickle jars or tins may be used. I prefer deep, narrow biscuit tins if they are to be had. The receptacle used should be sunk until its upper edge is exactly on a level with the bottom of the run, and this must be made quite smooth to the edge. Pieces of slate or tile are now laid on the sides, leaving an

aperture not less than the width of the run. The sides of the run must be built up with brick or pieces of wood and the whole covered with a slate or flat stone to keep out all light. The pitfall is now complete and may be examined once a day. Do not place this trap near fresh workings or the mole will fill it with earth pushed along the run. When I took charge of these gardens several years ago the place was infested with moles. By a free use of this trap in the main runs their numbers were quickly reduced, and in two or three years they disappeared altogether, and the main runs went out of use and gradually filled up. This proves the trap to be well worth the trouble taken in making it. It is a pity one has to destroy the creature, for in its proper sphere it does an immense amount of good by destroying vast numbers of injurious larvæ underground. There are some who would like to see it banished from their gardens without destroying it, and I would advise them to open main runs and workings and place a handful of Alphon or Vaporite in them and replace the soil. This will be found a good preventive, and must be repeated whenever the mole makes a fresh attempt.

The long-tailed field mouse (*Mus sylvaticus*) is a serious pest in most gardens, working sad havoc with sprouting Beans and Peas, eating ripe Grapes in the vinery and digging up Crocus bulbs. Nothing is safe from its ravages, up or down, for it can climb like a squirrel and dig well too. For its destruction I would like to make more widely known a trap which is at once simple, certain and humane. To make this trap two bricks and a piece of small, stiff wire are required. I use 10-gauge galvanised wire, which does well. Cut off a piece of wire 4½ ins. in length and bend the ends into open curves like an S with a long, straight shank, making it when finished exactly 3 ins. in length. Now take some peas which have been soaked in water for one or two days or, better still, sprouted in damp moss, and thread four or five on to the straight shank of the wire. If the ends are sharp and nicely curved, the peas will go

on without breaking. This is a deadly bait for these mice, and in autumn and winter will often last a fortnight or more without being renewed. Now place one brick on edge and make the soil in front firm and level, then lay the other brick in front of and fitting close up to the upright one, raise it on its edge away from the upright, and place one end of the baited wire in the centre and 1½ ins. from its upper edge and the other end ½ in. from the lower edge of the upright brick. This is the point of lightest balance if the wire is the correct length, and the lightest pull on the

bait will bring it down. The larger slugs are often victims. The bricks used must be fairly smooth ones. If set against a wall only one brick is used, but a smooth place must be selected. Another excellent trap is the break-back, and the pattern with the small trigger should be chosen, not that which has the front half cut through to form a trigger. These traps can be used with or without bait. Place the trigger end against a wall and

THE BRICK TRAP AND ITS VICTIMS.

place a tile or length of board on either side to form a V with a space between the ends and the wall to allow the mice to pass on to the trap. When rows of Beans or Peas are attacked use a trap in the same way at each end, the V pointing inwards and the trigger end of the trap across the small space left at the apex. No bait is needed and the marauders are soon caught. To prevent the loss of the traps I drill a small hole near one of the rear corners and secure to a small stake with string.

The field vole or short-tailed field mouse (*Microtus agrestis*) is a common pest, and in some seasons will attack growing crops of Beet and Carrots, and work havoc among Cauliflowers and winter Broccoli when lifted and stored in sheds. It will eat almost anything in the way of fruit, nuts, seeds, grass, and root and stem vegetables. In grass land they are easily caught in pitfalls dug across their runs. Holes about 18 ins. or so in depth, with the bottoms much wider than the tops, are made, as the voles are unable to climb up the inward sloping sides. When growing crops are attacked, place boards on edge on that side of the plot where they enter. Short lengths are best, with 1½ in. spaces between the ends and a break-back trap set with its trigger across the opening. Some can be driven into the traps by walking slowly through the crops towards them. Examine the traps often through the day and reset where necessary and their ravages will soon cease. If the garden is near a stream or pond, the water vole is often very destructive, especially in the winter. These may be taken in the same way, but the stronger break-back made for the rat is necessary. The wire cage traps baited with Apples are also good. A small-bore shot-gun is useful for shooting them at the water's edge.

Of that offensive and voracious pest, the rat, I much regret to say there is no simple way of taking it. It is far too cunning for that and is about the worst four-footed pest we have, doing damage of every sort—nothing coming amiss to its appetite. It takes toll of everything, from ducks to green peas, and acts as

WHERE TO SET A BREAK-BACK TRAP.

scavenger besides. I am no advocate of steel traps and poisons on account of their cruelty and danger to friend and foe alike, but against such a cunning and destructive pest as the rat one feels entitled to use any and every means, whether fair or foul, to destroy it. A good substitute for poison is to feed with meal in a dry place for a few nights and, when it is taken freely, mix a quantity of plaster of Paris with the meal and place saucers of water near. It is well to wear leather gloves when setting any kind of trap, as the rat's sense of smell is very keen. Wire traps

should have the bottom wires lightly covered with soil, as the rat will rarely tread on bare wires or metal of any kind. A plank leant against a wall with two steel traps, jaws pointing outwards, is often successful. When rats change their quarters they generally do it on moonlight nights, and traps should be freely set on these nights, as rats are more easily caught on strange ground. A good sharp terrier is invaluable, and his work may be assisted by a gun and ferrets.

Lingfield.

H. C. Wood.

(To be continued.)

Weeping Mulberry needs careful training until an adequate length of trunk is obtained.—A R

THE "HUNTINGDON" WILLOW.

IN "Answers to Correspondents," issue December 10, you say you have not heard of "Huntingdon" Willows. I have been familiar with this name for fifty years. Many nurserymen catalogue *Salix alba* under this name, Messrs. Thomas Perkins and Son, Limited, Northampton, and Messrs. Benjamin Reid and Co., Aberdeen, are two among them.—CHAS. A. BRUNNING.

IN your reply to your correspondent "W. W. T.," (THE GARDEN, December 16), *re* cricket-bat Willow, you state there must be some confusion in the name Huntingdon Willow. We have grown the Huntingdon Willow (*Salix alba*) for a number of years. It is one of the best growers we have.—K. AND J. HILL, *Willington*.

Salix alba is, of course, a well known tree, but as far as our experience goes the English name is White Willow. The true Cricket-bat Willow, *S. coerulea*, is by some botanists considered only a form of the White Willow, but Bean ("Trees and Shrubs") appears to agree with Henry that it is probably a hybrid between *S. alba* and *S. fragilis*. However that may be, the timber of *Salix alba* is useful enough, though not first-rate for cricket-bats.—Ed.]

CORRESPONDENCE

STRAWBERRIES AND ASPARAGUS.

DESPITE the long and severe drought of last summer, we managed here to get our new Strawberry-bed, from runners laid into small pots, finished the first week of August. Our date in average seasons has been the last week of July. The runners are always taken from a small separate bed of one year old maiden plants, *i.e.*, which have not been allowed to fruit. This makes all the difference in the world to the strength of the ensuing plants. They are set out only 1ft. apart each way, which gives room enough for the first year's fruiting. If we keep them a second year, we cut out every other plant with a sharp spade. But if labour and fresh ground are available, we grow all our Strawberries as annuals only: the crop is heavy enough and the quality very much better. It is a strange fact that well rooted plants are unobtainable from the trade until well on in August, and sometimes not before September. I suspect that the maiden plant system, which gives runners much earlier than from fruiting stools, is not generally in use. In vain do advertisements tell me that Strawberries supplied in September or October "fruit well the first year." They don't and can't. It was, I think, my very competent friend Mr. J. D. Pearson who replied to a former note of mine that the objection to such early planting lies in the necessity of watering. But who can say when rain will come in our climate and when it won't? Here, our plantation was well settled in by heavy rains immediately after the making, and now we have had scarcely a drop for the last two months. I have never had reason to repent of my practice of planting as early as possible and trusting to luck for rain. Asparagus surely tries to tell us by its great resentment of root disturbance that transplanting violates its nature and the rational way is to grow it from seed. It is difficult to understand why and when transplantation came into fashion otherwise than to sell plants. Here we always sow seed where it is to remain unmoved. The gain of time by transplanting is only one year, with the large *per contra* of outlay on bought plants and loss of vigour and durability.—G. H. ENGLEHEART, *near Salisbury*.

tastes so like stewed Apples that I think a blind-folded man would never find out the difference!—E. H. WOODALL.

THE WEEPING WHITE MULBERRY.

I WAS very interested in the article on Weeping Trees (THE GARDEN for November 18, page 579), in which reference is made to the Weeping White

THE WEEPING MULBERRY, MORUS ALBA PENDULA.

Mulberry, *Morus alba pendula*. I enclose a picture of a young tree at Lingfield, Surrey, which shews, I think, its value as a lawn tree. It is, I think, a little strange that there should be so many varieties of the White (Silkworm) Mulberry in cultivation, whereas the Common Mulberry (*M. nigra*) appears not to have varied from the type despite its long history in cultivation. The

CHRYSANTHEMUM

TOKIO.

ONE would have thought that Mr. E. H. Woodall had been a reader of THE GARDEN long enough to know that the space allotted in it for show reports has for many years been restricted to bare necessity. To discuss or even to criticise the Paris Show from an artistic point of view would require far more time and space than even the most indulgent editor could be expected to permit under existing circumstances. It is true we might learn something from French methods of arrangement. I have preached that for a generation at least, but it is equally certain that our English growers and exhibitors can teach the French something too. If Mr. Woodall had been at Le Mans and seen Mr. Jones' exhibit there last year, or if he had been to the Paris Show in 1911 and seen Mr. Thomas Stevenson's grand display when the show was held on the Cours-la-

Reine, he would have had ocular demonstration of the truth of that. To take individual groups, there is very little as a rule to learn from the ordinary French exhibit. They are often too low, too flat and painfully monotonous in their uniformity. The great charm of a French Chrysanthemum show is the total absence of long tables, in place of which is the design of the whole

THE LOQUAT.

I SEE that a gardening friend in New Zealand writes saying that there they do not eat the Japanese Medlar or Loquat when cooked! There is no accounting for tastes we all know, but this is especially surprising, for the raw fruit is rather acid and has very large seeds in it, so much so that there seems very little flesh for so much seed. But when stewed, the big seeds taken out and some sugar added, it is a welcome addition to the table in spring, coming in as it does before the Cherry and Strawberry. Properly cooked it

show, in which the various groups are tastefully filled into a kind of artistic framework. Exceptionally, like that of Paul Féron this year, we get a glimpse of originality, but surely some of the great stretches of low, flat groups such as we saw last October in the Palmarium need not be imitated in England. The covering up of the pots, the hiding of the receptacles in which the cut blooms are placed, the green turf edgings to the groups and the frequent laying down of grass lawns on which to display their gains are all of some decorative value to the French exhibitors, and might be usefully introduced here. But the Palmarium of the Jardin d'Acclimatation is not by any means an ideal site.

My chief concern is to congratulate Mr. Woodall on his having discovered Tokio, the Chrysanthemum I mean, of course, not the place, which is properly called Tokyo. It is not apparent whether he first saw it this year or last, but it is evident that although he is resident in France, Mr. Woodall has not had much experience of the Paris Autumn Show. As an exhibition flower Tokio is absolutely unknown in this country, and it is not difficult to say why. These thin, tubular, stiff-petalled Japs of the hedgehog type have the colour inside, and only shew that of the reverse. There has been quite a number of them raised in France from the days of Simon Delaux, if not before, but they have never appealed to British growers. They are useless in the cut bloom classes, and, to-day, trained specimen plants are no longer grown here for show as of yore. In spite of that I have always regarded Tokio as one of the most telling varieties for specimen plants. To my knowledge it is one of the oldest varieties in cultivation—it is not a modern one as Mr. Woodall might lead his readers to suppose. Tokio has been shown in Paris for sixteen years at least, so that by no effort of the imagination can it be described as a novelty. I saw it for the first time at the Paris Show of 1905, and referred to it in my report for the *Gardener's Magazine* at the time. Two years later Vilmorin's group was staged in the corridor which linked up the two large greenhouses on the Cours-la-Reine, previously known as the Palace of Horticulture in the great Universal Paris Exhibition of 1900. This is what I wrote of it in my report after describing the Vilmorin exhibit in the *Gardener's Magazine* for November 23, 1907: "In the middle of this lawn was an immense trained specimen of Tokio, a pale pink variety of Japanese, peculiarly suited for this kind of culture. The plant must have been not less than 8ft. or 9ft. in diameter, and bore 7, 8 fully expanded blooms." A picture of that group was given in the *Gardener's Magazine* for November 23rd, 1907; in the *American Florist* for the 30th of the same month; and in *Horticulture*, of Boston, U.S.A., for the same date, shewing Tokio as a prominent plant in the Vilmorin exhibit. We certainly did not see Tokio in anything like that form at the recent Paris Autumn Show.—C. HARMAN PAYNE.

We should not ourselves describe a variety of Chrysanthemum sixteen years old as "one of the oldest in cultivation" when we remember that such old stagers as George Glemny and Mrs. Ruddle are still grown. [Ed.]

THE TWELVE BEST SHRUBS.

I ENCLOSE two lists each of a dozen shrubs which have grown in my garden for the last ten years and are quite hardy, and may be of interest to readers in the North of Scotland. My garden is in Glendevon, Perthshire, on the Obil Hills, about 700ft. above sea-level, and shrubs flower fully a fortnight later than those near the sea, such as Edinburgh Botanic Gardens. I have not included Rhododendrons and Azaleas,

which I may say do well with me. The soil is rather light, with a little peat and very stony. Being near the hills we get a good deal of moisture even in a dry summer, and all varieties of conifers grow well, also the Himalayan Gentians-Farreri and sino-ornata, and the different species of Himalayan Meconopsis. List 1.—*Ribes sanguineum atrosanguineum*, *Forsythia suspensa*, *Berberis stenophylla*, *Spiræa arguta multiflora*, *Dentzia crenata magnifica*, *Osmanthus Delavayi*, *Lilac Mme. Lemoine*, *Rubus deliciosus*, *Philadelphus Virginal*, *Viburnum plicatum* (on wall), *Viburnum Carlesii* and *Hypericum patulum Henryi*. List 2.—*Cydonia Maulei atrosanguinea*, *Cytisus precox*, *Hydrangea paniculata grandiflora*, *Potentilla Farreri*, *Spiræa Veitchii*, *Prunus triloba fl. pl.*, *Escallonia Philippiana*, *Cistus laurifolius*, *Genista virgata*, *Weigela Eva Rathke*, *Cotoneaster multiflora* and *Andromeda floribunda*.—A. H.

A USEFUL TRAILING CAMPANULA.

IN "A Selection of Fuchsias," which you published in *THE GARDEN* dated December 2, I notice an error in the name of one of the varieties mentioned, probably due to my bad writing. "Pink Paul" should be "Pink Pearl," and although the mistake is not of great importance, perhaps you will insert a note correcting it in a forthcoming issue. I should like to draw attention to a very beautiful little *Campanula* called *haylogensis*. This variety is of delicate growth and trailing habit, while from July onwards until late autumn it bears pretty violet blue flowers in great profusion which, though small, are very effective for the greenhouse. *Campanula haylogensis* is offered in the hardy plant catalogue of Messrs. John Waterer, Sons and Crisp, and,

while it is probably at its best on a rockery, I would strongly recommend anyone who requires a plant for the front of a greenhouse stage to give it a trial. The illustration of the flowers and fruit of *Fuchsia procumbens* on page 607 is very interesting, and I hope you will see your way to publish illustrations of different types of the *Fuchsia* family from time to time.—CECIL M. BAILEY.

THE SCOTCH MARIGOLD.

OF the value of the Scotch Marigold, *Calendula officinalis*, as a bedding annual I have been long aware, but not until the middle of last month did I discover its worth as a flower for lasting well when cut for vase work, the flowers keeping fresh for nine days to a fortnight, according to their stage of development when put in the vase. I ascribe my belated discovery to the fact of there being so many choicer plants from which to gather during the earlier part of the year that the Marigold, like many another plant, gets passed by when one is looking for something fragrant or more attractive for the special table or desk. The gathering of the flower under notice was made from a large bed of *Calendulas* (among which had been interspersed *Eschscholtzia californica*) and which formed part of an arrangement of beds containing brown and gold flowers. In the cut state they associate well with bronze and terra-cotta single *Chrysanthemums*. The colour of this Marigold always seems richer or deeper in tone in autumn than it does in summer, but I suspect such a notion is an illusion, the reason being that the flowers look brighter on account of the greater greyness of sky at this season and the much diminished strength of light.—C. T.

GARDENING OF THE WEEK

GREENHOUSE AND CONSERVATORY.

Epiphyllums are generally regarded as requiring more heat than the average greenhouse affords. It is true that they enjoy a higher temperature while growing, but when in flower they, like many other plants that enjoy similar conditions during their growing season, stand quite well in an ordinary heated greenhouse. These plants are valuable as they usually flower during the winter months. They were at one time much more commonly cultivated than they are at present, being in fact, grown in considerable quantities for the London market; then there were quite a number of varieties which, at the present day, seem to have disappeared from cultivation. The two species, *E. truncatum* and *E. Russellianum*, and *E. Gaertneri*, which is supposed to be hybrid, are still frequently met with, and large specimens are not uncommon in out of the way gardens. Their drooping habit renders them specially suitable for baskets or for growing as small standards. They root quite readily from cuttings, but are usually grafted on stocks of *Pereskia aculeata*, especially when standards are required. The operation of grafting is quite easy: the stock should be cut over at the required height and a slit made on the top, into this insert a piece of *Epiphyllum*, the bottom part of which is cut to a wedge-shape, bind with raffia or soft cotton, or simply run a spine or two of the *Pereskia* through the stock and scion and the operation is complete. Being rather spare rooting plants, ample drainage must be given, and the compost, which should consist of good medium loam, should have a quantity of broken bricks or old mortar rubble added to it. Beyond careful watering at all times, their cultivation is not at all difficult.

Succulent Plants.—In its widest sense the term "Succulent" includes a very wide range of plants, varying from giant *Euphorbias* to tiny *Mesembryanthemums* and *Sedums*. At one time these plants were very popular, and there were many good collections in gardens up and down the country. They have always been favourites with amateurs; this due, no doubt, to the fact that a small greenhouse will house quite a large collection

of the smaller and choicer species. They also require very little attention in the way of watering, even during the summer there is little chance of their suffering if they are not watered every day. One must not infer from this that they should be neglected in this respect. During the winter months they require very little water, and in a cool greenhouse many of them will stand for several weeks without it. Care should, of course, be taken that the plants do not shrivel. As damp is their chief enemy during winter a buoyant atmosphere should be maintained. If any re-potting is required it should be done early in the New Year. The plants then have a good chance to get well established during the summer; on the other hand, if plants are in bad condition at the root they may be safely repotted at any time. After re-potting very little water should be given until they have made fresh roots. Quite a number of sorts are excellent for growing in a sunny window and two at least, viz., *Aloe variegata* and *Cereus flagelliformis* (the Rat's-tail Cactus), are usually seen in better condition in cottage windows than in greenhouses. *Cereus grandiflorus* and *C. nycitcalus* are both night-flowering and are well suited for training on the wall or under the roof glass of a warm greenhouse. Among *Cotyledons*, *Sempervivums*, *Crassulas*, *Mesembryanthemums*, *Aloes*, *Agaves*, *Mammillarias*, *Phyllocacti*, *Gasterias* and *Haworthias*, there is ample choice for anyone who is interested in this class of plants.

Clematis indivisa lobata.—This beautiful climber is a native of New Zealand and in Cornwall is hardy on warm walls, but generally it requires the shelter of a cool house and in my experience it always does best in a house from which frost is just excluded. If the house is too warm this plant is generally attacked by mildew. When doing well it produces its starry white flowers in wonderful profusion. As the flowers have long stalks they are very useful for cutting. The plant can easily be increased by layers or by means of internodal cuttings, which should be inserted in pots of sandy soil and stood under a bell glass in a cool house.

Royal Botanic Gardens, Kew.
